The work contains a description and an analysis of two different approaches determining the connections between quantal and classical theories.

The first approach associates with any quantum-mechanical system with finite number of degrees of freedom a classical Hamiltonian system ‘living’ in projective Hilbert space $P(\mathcal{H})$, and it is called here the ‘classical projection’.

The second approach deals with ‘large’ quantal (= quantum mechanical) systems in the limit of infinite number of degrees of freedom and with their corresponding ‘macroscopic limits’ described as classical Hamiltonian systems of the system’s global (intensive) quantum observables.

The last part of this work contains a series of models describing interactions of the “small” physical (micro)systems with the “macroscopic” ones, in which these interactions lead to a (macroscopic) change of some “classical” parameters of the large systems. These models connect, in a specific way, the two classes of the systems considered earlier in this work by modeling their mutual interactions leading to striking (i.e. theoretically impossible in the framework of finite quantum systems) results.

The projective space $P(\mathcal{H})$ of any complex Hilbert space $\mathcal{H}$ is endowed with a natural symplectic structure, which allows us to rewrite the quantum mechanics of systems with finite number of degrees of freedom in terms of a classical Hamiltonian dynamics. If a quantum-mechanical system is associated with a continuous unitary representation $U(G)$ of a connected Lie group $G$ on $\mathcal{H}$, the orbits (possibly factorized in a natural way) of the projected action of $U(G)$ in $P(\mathcal{H})$ are naturally mapped onto orbits of the coadjoint representation $\text{Ad}^*(G)$ of $G$. These coadjoint orbits have a canonical symplectic structure which coincides with the one induced from the structure of $P(\mathcal{H})$. For important classes of physical systems these symplectic spaces are either symplectomorphic to the ‘corresponding’ classical phase spaces, or they are some extensions of them (describing, e.g. particles with ‘classical spin’). Quantal dynamics is projected onto these phase spaces in a natural way, leading to classical Hamiltonian dynamical systems without any limit of Planck constant $\hbar \to 0$.

For a large (infinite) quantal system an automorphic group action of $G$ on the $C^*$-algebra $\mathfrak{A}$ of its bounded observables enables us to define a macroscopic subsystem being a classical Hamiltonian system of the same type as we obtained in the case of finite number of degrees of freedom. There is a difference, however, between the interpretations of ‘classical projections’ and of these ‘macroscopic limits’: The classical (mechanical) projection describes classical mechanics of expectation values of quantal observables whereas the macroscopic limit describes a quantal subsystem with classical properties - its observables are elements of a subalgebra $\mathfrak{M}_G$ of the center $\mathfrak{Z}$ of the double dual $\mathfrak{A}^{**}$ of $\mathfrak{A}$. Any state $\omega$ on $\mathfrak{A}$ has a unique ‘macroscopic limit’ $p_{M\omega}$ which is represented by a probability measure on the corresponding (generalized) classical phase space. This offers us a possibility of deriving a classical (macroscopic) time evolution
(which is, in general, in a certain sense stochastic, cf. [29, Sec.III.G]) from the underlying reversible quantal dynamics.

A scheme of ‘macroscopic quantization’ is outlined, according to which a (nonunique) reconstruction of the infinite quantal system \((\mathfrak{A}; \sigma_G)\) from its macroscopic limit is possible. By determining a classical Hamiltonian function in the macroscopic limit of \((\mathfrak{A}; \sigma_G)\) we can define a ‘mean-field’ time evolution in the infinite system \((\mathfrak{A}; \sigma_G)\). Our definition of the ‘mean-field’ evolutions extends the usual ones. The schemes and results developed in the work are applicable to models in the statistical mechanics as well as in gauge-theories (in the ‘large N limit’). They might be relevant also in general considerations of ‘quantizations’ and of foundations of quantum theory.

The last Chapter of this work is devoted to the description of several models of interacting ‘microsystems’ with ‘macrosystems’, mimicking a description of the ‘process of measurement in QM’. In these models, certain ‘quantal properties’ of the system, namely a (coherent) superposition of specific vector states (eigenstates of a ‘measured’ observable), transform by the unitary continuous time evolutions (for \(t \to \infty\)) into the corresponding ‘proper mixtures’ of macroscopically different states of the ‘macrosystems’ occurring in the models.

In this connection we shall shortly discuss the old ‘quantum measurement problem’, which however, in the light of certain experiments performed in the last decades and suggesting the possibilities of quantum-mechanical interference of several macroscopically different states of a macroscopic system, need not be at all a fundamental theoretical problem; this might mean that the often discussed ‘measurement process’ can be included into the presently widely accepted model of quantum theory.

Acknowledgements:

This work is a revised and completed version of the unpublished text: “Classical Projections and Macroscopic Limits of Quantum Mechanical Systems” written roughly in the years 1985 - 1986. The author is indebted to Klaus Hepp for his stimulations and the kind help with correcting many formulations of the original text. During the work on the old text, encouragements by Elliott Lieb and by the late Walter Thirring were also stimulating, and the discussions with the colleagues, the late Ivan Korec, Milan Noga, Peter Prešnajder and Jiří Tolar, were useful and the author expresses his gratitude to all of them. Thankfulness for several times repeated encouragements to publish the old text should be expressed to Nicolaas P. Landsman. Author’s thanks belong also, last but not least, to his colleague Vladimír Balek for his kind help with final formulation of important parts of this book.

Technical notes:

(a) This book contains several technical concepts which are not introduced here in details. The readers needing to get a brief acquaintance with some additional elementary concepts and facts of topology, differential geometry (also in infinite dimensions), group theory, or theory of Hilbert space operators and theory of operator algebras, could consult e.g. the appendices of the freely accessible publication [37], and the literature cited in our
Bibliography. Due to connections of many places in the text of this book with the content of the work [37] it is recommended to keep the cited [37] as a handbook. The frequent citations from [37] contain usually references to specific places of the cited work.

(b) Two kinds of quotation marks are used: Either the ones which stress some “standard expressions”, or those which indicate ‘intuitive denotations’. The difference between these two is not, however, very sharp.

(c) Many symbols appearing in mathematical formulas are introduced in various places of the text and repeatedly used in the rest of the book. For easier revealing of their meanings, they are included into Index and their first appearance in the text is stressed, sometimes in a not quite usual manner, by **boldface form** of a part of the surrounding text.

Introduction

1.1 Motivation and Summary

1.1.1. Successful communication and manipulation with ‘objects’ requires construction of some adequate theoretical models (≈ theories) of some classes of ‘objects’, resp. ‘phenomena’. Different phenomena might be described by different theoretical schemes. These schemes should be, however, mutually consistent in the sense giving the same results for phenomena lying in the common domain of applicability of different theories. If one of the theories is considered to be ‘more general’ then a second one, then the whole domain of applicability of the second theory has to be contained in the domain of the first one. This is the case of quantum mechanics (QM), which is believed to be a ‘covering theory’ of the more special classical mechanics (CM) - to the extent of measurement precision of apparatuses determining of ‘classical systems’. Hence we can ask how to describe phenomena belonging to the domain of applicability of CM in the framework of QM.

1.1.2. Any single phenomenon, which is unambiguously and reproducibly determined by a specification of an empirical situation is, however, expressible in terms of parameters (resp. variables) occurring in CM: coordinates of positions and velocities of points distinguished and measured by ‘macroscopic bodies’ and various correlations between these variables. Hence also any experimentally realizable situation described in QM (which need not be a consequence of laws of CM, e.g. observation of spectra of atoms) is expressible in terms of CM (e.g. preparation of sources of radiation and measurement of positions of spectral lines displayed on screens). Quantal (:= quantum mechanical) phenomena are not only observed on a ‘background’ and ‘from the point of view’ of quantities describing states of macroscopic bodies (resp. of such parameters, the behaviour of which is adequately described by laws of CM), but also specific theoretical models for description of such phenomena in the framework of QM are constructed under strong influence of existing models in CM (e.g. the quantal models of atoms compared to classical planetary motions, or, more generally, some systems of canonically conjugated observables in the sense of the Hamiltonian CM correspond isomorphically to a subset of quantal observables). Quantal models of many systems, on the other hand, might be constructed from classical models of the same systems (which are adequate in a certain range of conditions, e.g.
classical gases in some intervals of temperature and density) by a more or less standard procedure of ‘quantization’, compare, e.g. [19, 93, 117], [225, 228, 314], and works quoted therein. The (vaguely stated) question arising from these considerations is: **What is a ‘physically justified way’ of correct determination of quantal models from their classical approximates?**

1.1.3. One of the remarkable features of QM is the occurrence of the universal (Planck) constant $\hbar$, which might be used to measure mutual ‘deviation’ of quantal and classical descriptions of a given physical system (we shall not discuss here the nontrivial methodological question: how to determine a ‘physical system’ and what is its dependence on theoretical concepts used in the process of the determination). Consequently, an approximate description of processes in the framework of QM that are characterized by some quantities $S$ large compared to the Planck constant ($S$ being of the same physical dimension as $\hbar$) is often reached in the limit of large values of $S\hbar^{-1}$ (‘short wave asymptotics’). If, however, the system described by QM has some features (‘variables’ etc.) which are adequately described by CM too, then the description of this ‘classical subsystem’ has to be contained in QM with the fixed value of Planck constant (i.e. the classical description should be exact consequence of QM without any approximation procedure, which is often formally performed by the limit $\hbar \to 0$). We shall introduce a standard procedure of obtaining classical systems from quantal ones. Such a classical system is called here a ‘classical projection’ of the quantal system (contrary to the ‘classical limit’ obtained in some way by $\hbar \to 0$).

1.1.4. This work is considered as a conceptually and intuitively (however, not always technically) simple way to give some insight into the indicated questions. Much more complete and extensive overview of these and related technical topics is given in the recent book [192] by Landsman. Many relevant questions are discussed in the author’s work [37], containing also a detailed discussion of possible extensions of the QM formalism to its nonlinear versions; these nonlinear quantum motions are closely connected with the theory presented in our Chapter 6, corresponding to the motions of a single “microsystem” moving in the “mean-field” acting on it by interaction with infinite number of similar microsystems; the dynamics of the whole infinite collection of “microsystems” is, however, linear. Such a nonlinear quantum dynamics is also discussed by S.Weinberg in [328], whose work is also discussed and reformulated in [37, Sec.3.6].

The mentioned work of S.Weinberg is not intrinsically consistent in the case of nonlinear motions of nontrivial density matrices, resp. “mixtures”. To obtain successful picture of nonlinear quantum dynamics of “mixed states” together with their physically satisfactory quantal interpretation, one has to introduce two kinds of “mixed states”: The usual one used in (linear) QM are described in the standard way by density matrices (called there “elementary mixtures”), and others are called “genuine mixtures” (or. also “proper mixtures”) - these correspond to the states which arose by a real ‘mixing’ of different quantal states, as it appears in classical statistical mechanics in ensembles of systems occurring in different states - different points of the phase space of the described system; they are introduced in [37, Sec.2.1-e] and difference of these two kinds of mixtures is illustrated e.g. in [37, Sec. 3.3-e].

---

1Consider here macroscopic quantal effects (e.g. superconductivity, superfluidity) vanishing for $\hbar \to 0$. 

1.1. MOTIVATION AND SUMMARY

In the remaining sections of this introductory chapter it is specified briefly what we mean here by QM, CM and by the ‘quantum theory of large systems’. The second chapter is devoted to a detailed study of geometry of the projective Hilbert space \( P(\mathcal{H}) \), where \( \mathcal{H} \) is the Hilbert space used in description of a quantal system. We emphasize there the natural symplectic structure on \( P(\mathcal{H}) \), cf. e.g. [7, 214, 37, 231]. This structure is used in Section 2.3 to description of QM in terms of infinite dimensional CM, i.e. of classical Hamiltonian field theory with, however, the standard quantum statistical interpretation.

1.1.5. The Chapter 3 “Classical Mechanical Projections” is devoted to a general construction of Hamiltonian CM from a given quantal system (provided that an interpretation of its ‘basic quantities’ is specified by a unitary representation \( U(G) \) of a Lie group \( G \); for Lie groups see e.g. [13, 50, 209, 247]). The scheme of this construction is very simple: Take the orbit \( O_\varrho := G.\varrho \) through a point \( \varrho \in P(\mathcal{H}) \) of the action of \( U(G) \) on \( P(\mathcal{H}) \) corresponding to the action of \( U(G) \) on \( \mathcal{H} \) and restrict the natural symplectic form on \( P(\mathcal{H}) \) onto \( O_\varrho \). For properly chosen \( \varrho \) the orbit \( O_\varrho \) is an immersed (and regularly embedded, cf. [37, Proposition 2.1.5(iv)] completed by [47]) submanifold of \( P(\mathcal{H}) \subset \mathfrak{H}(\mathcal{H}) \) (cf. 1.2.3), hence the restriction is well defined. The obtained two-form on the manifold \( O_\varrho \) might be degenerate, but after a natural factorization of the orbit we obtain a symplectic manifold which is symplectomorphic to an orbit of the coadjoint representation \( Ad^*(G) \). Symplectic manifolds obtained in this way are interpreted as classical phase spaces. In some cases, if the generator of time evolution (the Hamiltonian operator) belongs to the generators of \( U(G) \), we can obtain from the symplectic structure of \( P(\mathcal{H}) \) a contact structure on \( O_\varrho \) which reproduces an ‘extended phase space’ (odd dimensional) of classical mechanics. If the Hamiltonian is not a generator of \( U(G) \) (i.e. if \( G \) is only a ‘kinematical group’ without representing any time evolution), the quantal dynamics might be in some cases naturally projected onto the obtained classical phase space as a globally Hamiltonian complete vector field; this situation is analyzed in Section 3.3.

Although such a construction of CM from QM is equally applicable to any quantal system (specified by some \( U(G) \)), the interpretation of the obtained classical system depends on the specific physical system, and also on the physical quantal state \( \varrho \) from which the orbit \( O_\varrho \) is constructed. In any case, it is obtained a formal procedure for construction of ‘classical projections’ from arbitrary (finite) quantal systems.

Chapter 4 provides some simple examples of this formal procedure. In the subsection 4.1.6, we obtain from a simple nonrelativistic quantal system with the potential energy \( V \) the corresponding classical system (in the conventional quantal sense) with a modified potential energy, where the modification depends on the choice of the ‘initial state’ \( \rho \in P(\mathcal{H}) \) (for the orbit \( O_\varrho \) and can be made arbitrarily small (in the sense of weak convergence of distributions to the distribution \( V \)).

For a general time evolution, the orbits \( O_\varrho \) are not invariant with respect to the quantal time evolution, and also on various orbits of the same quantal system the projected classical evolutions are mutually different. This brings in mind an idea of some stochastic time evolution on a classical phase space reflecting the underlying quantal evolution.

Such an idea is not, however, realizable for systems with finite number degrees of freedom (briefly: finite systems) because their density matrices have not unique decomposition into
convex combinations of pure states \( \varrho \in P(\mathcal{H}) \). This is just a crude intuition which was not clearly formulated and realized in the following text.\(^2\)

1.1.6. Quantal systems with infinite number of degrees of freedom (briefly: infinite systems) are considered in the Chapter 5. A physical motivation for such a consideration connected with our investigation of the relations between QM and CM consists in the fact, that 'macroscopicality' and 'classicality' are almost synonyms: most of physical systems containing an operationally well defined classical subsystem are compound of a large number (say: of the order \(10^{20}\) and more) of microscopic constituents (like atoms) and vice versa.\(^3\) Described approximately as infinite quantal systems, these systems have some characteristic properties distinguishing them from finite ones: the existence of nontrivial sets of 'classical observables' in given representations of observable algebra (this fact is a consequence of the existence of various inequivalent unitary representations), the existence of quite a rich simplexes (in the sense of Choquet) in the state space of the system allowing (in the presence of some additional assumptions) unique decomposition of their elements into extremal elements etc. This enables us to describe their 'classical subsystems' directly in terms of the quantal description - hence the name 'macroscopic limit'. This means that, contrary to the case of finite systems\(^4\), in the case of infinite systems quantal and classical interpretations of the 'macroscopic observables' coincide (at least on a \(G\)-invariant subset of states): classical, resp. macroscopic quantities are represented by operators belonging to the center of the weak closure of the algebra of observables in some representations.\(^5\)

1.1.7. The Chapter 5 is divided into two sections. In the first one we consider the system consisting of denumerably infinite number of quantal subsystems, each of which is described by a \(G\)-covariant representation of its algebra of bounded observables. To be more specific, we consider a sequence of copies of the same finite system in the (infinite) complete tensor product representation on a nonseparable Hilbert space \(\mathcal{H}_\Pi\). The representation \(U(G)\) describing an elementary subsystem determines a unitary (discontinuous) representation \(U_\Pi(G)\) on \(\mathcal{H}_\Pi\) which, in turn, determines an automorphism group \(\sigma_G\) of the algebra \(\mathfrak{A}_\Pi\) of quasilocal observables of the infinite system. A natural definition of a classical subsystem of the large quantal system \((\mathfrak{A}_\Pi; \sigma_G)\) appearing in this case can be extended to the case of arbitrary systems \((\mathfrak{A}; \sigma_G)\), as it is shown in Sec.5.2. The arising classical (macroscopic) subsystem \((\mathfrak{M}; \sigma_G)\) is naturally mapped into the classical Poisson system \((G^*; \text{Ad}^*(G))\), or to its generalizations.

1.1.8. Chapter 6 is devoted to an application of Sec's 5.1 and 5.2:

\(^2\)Some more specific hints on this possible classical stochastic evolutions from quantal time development could be found perhaps in [29].

\(^3\)The macroscopic quantal effects like superfluidity and superconductivity are additional effects observed in these 'classical subsystems' of the large quantal systems.

\(^4\)where the quantal interpretation of classical quantities (i.e. expectation values of generators of \(U(G)\) in corresponding states) was different from the classical interpretation (i.e. sharp values of corresponding classical generators)

\(^5\)The center \(Z(\mathfrak{A})\) of a \(C^*\)-algebra \(\mathfrak{A}\) is the commutative \(C^*\)-subalgebra of \(\mathfrak{A}\) consisting of all elements of \(\mathfrak{A}\), each commuting with all elements of \(\mathfrak{A}\): \(Z(\mathfrak{A}) := \{ z \in \mathfrak{A} : z x - x z = 0, \forall x \in \mathfrak{A}\} \).
It is shown that ‘mean-field’ type time evolutions can be determined on a large quantal system \((\mathfrak{A}; \sigma_G)\) by specification of a Hamiltonian dynamics of a classical (macroscopic) Poisson system - the macroscopic limit of \((\mathfrak{A}; \sigma_G)\).

This is a perhaps simplest example of (infinite-)long-range interactions in many body systems. The correspondence between classical and quantum descriptions of systems appear there ‘selfconsistently’: The quantum theory of the entering ‘elementary subsystems’ is built ‘on the background’ of the classical ‘environment’ what is compound of the infinite collection of those ‘elementary subsystems’. The dynamics of a general class of such systems is described in Section 6.3, and the statistical thermodynamics of equilibrium states is introduced in Section 6.4.

A slightly alternative approach to these quantum mean-field theories is described in the papers [40, 41].

1.1.9. Finally, the Chapter 7 contains four exactly solved models of interaction of a microscopic quantal system with a ‘macroscopic’ one. Due to this interaction the macroscopic quantal system changes its classical state to a different one. Such a change of a macroscopic (classical) state can be interpreted as a change of a ‘pointer position, hence these models could be considered as models of ‘quantum measurements’ in the sense of Klaus Hepp [153]. The change of the macroscopic state is reached in the limit \(t \to \infty\) of infinite time, and the convergence in the first three models is very slow.

In the last of the described models (in Section 7.6) the ‘macroscopic’ quantal system is described as a finite collection of ‘small’ quantal systems. This leads to problems with an unambiguous definition of ‘macroscopic states’, since it is possible (formally, in this abstract theory) to observe interference effects between such different ‘macroscopic states’. To make clear the correspondence of quantum theory with observations, it would be necessary to introduce also quantum models of observation apparatuses used for detection of states of such a large but finite ‘macroscopic system’. Some discussion on this problem (including reports of observations of ‘macroscopic interference phenomena’) appeared in literature in last decades, cf. e.g. [195, 196, 190, 191, 192, 55, 56]. In the model of Sec. 7.6, the (large but finite) ‘apparatus’ radiates a Fermi particle escaping to infinity and, contrary to the other above mentioned models of Chap. 7, it converges very quickly to the final ‘almost macroscopic’ state.

1.1.10. Bibliographical notes.

The canonical symplectic structure (in the case of finite dimensions) on complex projective Hilbert spaces is described in [7]; in context of QM it appeared, e.g. in [17, 69, 268, 37]. Orbits of \(U(G)\) in the Hilbert space were introduced in the special case of Heisenberg group \(G\) in [125], and in general case in [176, 239] under the name ‘(generalized) coherent states’. John Klauder obtained CM on such orbits (or even on more general submanifolds of Hilbert space) from the quantal Hamilton principle restricted to corresponding orbits (resp. to ‘overcomplete sets of unit vectors’), see [176]. The orbits \(G.\varrho\) in \(P(\mathcal{H})\), and the functions \(\nu \mapsto f_A(\nu) := \text{Tr}(\nu A)\ (\nu \in G.\varrho)\), named (in the case of one-dimensional \(\varrho\) ‘covariant symbols’ by Berezin [18] or ‘lower symbols’.

Ideas of this kind could, perhaps, reconcile the basic idea of Niels Bohr [26, 27] on fundamental role of a “classical background” in formulations of QM with the postulate that QM is the basic theory.
by Simon [291], were used for determination of bounds for quantum partition functions (see [199, 291]) in time dependent Hartree-Fock theory [268], and also for description of specific types of unitary representations of Galilean and Poincaré groups [2]. Some essential properties of generalized coherent states are described in [84]. The natural symplectic orbits of coadjoint representations was introduced in [174].

A further development of these (mathematical, as well as physical) ideas is also contained in the work [37, 47], which contains also a nonlinear extension of the formulation of QM. This nonlinear extension is also compared in [37, Sec.3.6] with the Weinberg attempt [328] to formulate a nonlinear version of QM.

Some of the main ideas on connections between QM and CM leading to the present work are implicitly contained already in the classical work [330]. The idea and techniques used for transition to infinite systems was gained mainly from works by Haag, Hepp, Lieb, Neumann, Ruelle and others (see e.g. [139, 155, 227, 271], and for a review compare [53, 54, 106]). A transition to macroscopic limit (‘statistical quasiclassics’) is described in [17] for a specific choice of the group $G$ and a mean-field type interaction. A review of works on macroscopic limits (‘large N limits’) is given in [342]. An attempt of the description of classical quantities of large quantal systems analogous to the here presented one is described in works by Rieckers with collaborators [265, 101], and by Morchio with Strocchi [221, 222]; see also the works [317, 318, 319, 320] by Thomas Unnerstall. A preliminary outline of a part of this work is contained in [32], and also in [40, 41]. The necessary mathematics can be found in the cited monographs, cf. also Appendices in [37].

An alternative way of description of thermodynamics and dynamics of quantum mean-field systems was later proposed in the work of the group around R.F.Werner, see e.g. [100].

A new approach to the theoretical description of classical (macroscopic) systems in the framework of quantum theory in a unique mathematical formalism is presented in a series of papers by Jean-Bernard Bru and collaborators [60].

1.2 Quantum Mechanics

1.2.1. In formal schemes of all theories considered in this work, the basic concepts are ‘states’, ‘observables’ and their transformations ascribed to a considered physical system. We shall not discuss here details of the empirical meaning of these concepts. Roughly, states are prepared by some standard empirical procedures and represent the situation, what has to be measured, observables describe (equivalence classes of) measuring apparatuses (i.e. the role of their function in the theory) giving certain empirically obtained responses if applied to states, and transformations include time evolution of the system in given conditions as well as various changes of equivalent descriptions of the system (symmetries).

In this section, we shall outline a simple standard scheme of the formalism of nonrelativistic (resp. Galilean-relativistic) quantum mechanics of finite systems (QM), i.e. the nonrelativistic view on physical systems containing only finite number of their further indecomposable elementary constituents (particles, spins, . . . ).

7The concepts of “system”, and “physical system” are taken here to be as intuitively clear.
1.2. QUANTUM MECHANICS

1.2.2. Observables: A separable complex Hilbert space $\mathcal{H}$ corresponds to any physical system in QM. Let $\mathcal{L}(\mathcal{H})$ denote the set of all bounded linear operators from $\mathcal{H}$ to $\mathcal{H}$, where the boundedness (equiv. continuity) is defined with respect to the norm of $\mathcal{H}$ coming from the scalar product $(x,y)$, $(x,y \in \mathcal{H})$, which is linear in the second factor $y$. Observables in QM (i.e. physical quantities empirically identifiable by some realizable(?) measuring devices) are represented by selfadjoint operators on $\mathcal{H}$ (in general unbounded). It is useful to consider along with any selfadjoint operator $A$ (corresponding to an equally denoted observable $A$) its spectral measure $E_A$ defined on Borel subsets of the real line $\mathbb{R}$ with values in projectors $E_A(\bullet)$ in $\mathcal{L}(\mathcal{H})$, $E_A(\mathbb{R}) = I := \text{id}_\mathcal{H}$ (:= the identity of the algebra $\mathcal{L}(\mathcal{H})$), cf. [37, Appendices B & C].

It is important to stress here, that in the conventional QM of finite systems (atoms, molecules, and finite collections of them) the set of observables contains the whole set $\mathcal{L}(\mathcal{H})$ of operators representing these observables. Hence, the algebra $\mathcal{L}(\mathcal{H})$ acts on $\mathcal{H}$ by the irreducible manner (i.e. no nontrivial subspace of $\mathcal{H}$ is left invariant). This also implies the impossibility, resp. inadequacy, of interpretation of the “mixed states” as representing some statistical mixture of systems occurring in the states decomposing the corresponding “mixture” (cf. 1.2.3) in this QM of finite systems.

1.2.3. States in QM are conventionally represented by density matrices, i.e. positive trace class operators $\varrho$ on $\mathcal{H}$ with unit trace (=the trace norm): $Tr(\varrho) = 1$. Density matrices form a convex subset in the linear space $\mathcal{T}(\mathcal{H})$ of all trace class operators which is closed in the trace norm $\|A\|_1 := Tr\sqrt{A^*A}$. Denote this set of states $\mathcal{S}_\varrho$. The extreme points of $\mathcal{S}_\varrho$ are represented by the one-dimensional orthogonal projectors $P_x \in \mathcal{L}(\mathcal{H})$ (projecting $\mathcal{H}$ onto one-dimensional subspaces $x$ containing $x$, $0 \neq x \in \mathcal{H}$). Any $\varrho \in \mathcal{S}_\varrho$ can be expressed as a weak limit of finite convex combinations of elements $P_j \in P(\mathcal{H}) := \{P_x : x \in \mathcal{H}, x \neq 0\}$ of the projective Hilbert space $P(\mathcal{H})$. We can write

$$\varrho = \sum_j \lambda_j P_j, \quad \sum_j \lambda_j = 1, \quad \lambda_j \geq 0. \quad (1.2.1)$$

The states from $P(\mathcal{H})$ are called pure states. The decomposition (1.2.1) of an arbitrary state $\varrho$ into pure states is highly nonunique if $\varrho$ does not belong to $P(\mathcal{H})$, hence the state-space $\mathcal{S}_\varrho$ is not a simplex, cf. [73], what is an important difference with respect to classical mechanics. This have important consequences for interpretation of the ‘mixed states’ described by density matrices $\varrho \notin P(\mathcal{H})$: The nonunique decompositions (1.2.1) show that these quantum states cannot be interpreted as representations of statistical ensembles each element of which (i.e. a copy of the considered physical system) occurs in a definite pure state, because pure states appearing in certain mutually different decompositions of the same density matrix are in general incompatible, i.e. they are eigenstates of mutually noncommuting (hence simultaneously nonmeasurable) observables, cf. [37, 1.5-b].

1.2.4. Quantum theories are ‘intrinsically (or irreducibly) statistical’, i.e. experimentally verifiable assertions can be expressed in general in terms of probabilities only in the frame of

---

8This point was important also in the discussion about (im-)possibility of deducing the linearity of QM-time evolutions from mere quantal kinematics together with the so called “No-Signaling Condition”, cf. [46].
these theories. Results of repeated measurements of a given quantity (observable) applied to
the same state (which should be, however, repeatedly prepared for each single measurement
because of its unavoidable disturbance by the interaction with the measuring apparatuses)
have a nonzero dispersion for a general quantity. The expectation value of measured values
of a given bounded observable (represented by the operator) $A = A^* \in \mathcal{L}(\mathcal{H})$ in the state
(represented by the density matrix) $\varrho \in \mathcal{S}_*$ is in QM expressed by

$$\omega_\varrho(A) := \text{Tr}(\varrho A).$$

(1.2.2)

$\omega_\varrho$ can be considered here as a positive linear functional on $\mathcal{L}(\mathcal{H})$, which is normalized (i.e. $\omega_\varrho(I_\mathcal{H}) = 1$) and normal (i.e. ultraweakly continuous), compare, e.g. [53, 54, 274]; the set of all such functionals $\omega$ might be identified with $\mathcal{S}_*$: to each $\omega$ corresponds a unique density matrix $\varrho =: \varrho_\omega$, for which $\omega = \omega_\varrho$ according to (1.2.2). For an arbitrary selfadjoint (not necessarily bounded) operator $A$, the probability of obtaining of its value in a Borel set $B \subset \mathbb{R}$, if measured in the state $\omega \in \mathcal{S}_*$, is

$$\omega(E_A(B)).$$

Here $E_A : B \mapsto E_A(B)$, is the unique projector valued measure of $A$, or its spectral measure, characterizing any selfadjoint operator $A$, [37, B & C]. We shall define also

$$\omega(A) := \int_\mathbb{R} \lambda \, \omega(E_A(d\lambda))$$

(1.2.3)

if the integral converges absolutely. This is a generalization, resp. an alternative form of (1.2.2). If $\omega_x \in \mathcal{S}_*$ corresponds to $P_x \in \mathcal{P}(\mathcal{H})$ and for a given $A = A^*$ the quantity $\omega_x(A^2)$ is defined (i.e. is finite), then $x \in D(A)$ (:= the domain of $A$), and vice versa.\(^9\)

1.2.5. Any observable $A$ determines a strongly continuous one-parameter group $t \mapsto \exp(-itA)$ of unitary transformations of $\mathcal{H}$ of which $A$ is its generator. This induces a weakly*-continuous (≡ $w^*$-continuous) group $\tau^A_t$ of *-automorphisms of the von Neumann algebra $\mathcal{L}(\mathcal{H})$ (cf. [37, B.2.1(v)]), $B \mapsto \tau^A_t(B) := e^{itA}Be^{-itA}$, $B \in \mathcal{L}(\mathcal{H})$, $t \in \mathbb{R}$, i.e. the functions

$$t \mapsto \omega(\tau^A_t B) := \omega(e^{itA}Be^{-itA})$$

(1.2.4)

are continuous for all $B \in \mathcal{L}(\mathcal{H})$ and all $\omega \in \mathcal{S}_*$. The observable $A$ represents in this way a one-parameter group of symmetries of the physical system. Conversely, any $w^*$-continuous one-parameter group of *-automorphisms of $\mathcal{L}(\mathcal{H})$ is given by an observable (determined up to an arbitrary additive real constant) in the above described manner (see e.g. [53, Example 3.2.35]). If $A$ is bounded, $t \mapsto \exp(-itA)$ is norm-continuous.

1.2.6. To obtain an empirical meaning of the formal scheme outlined above, it is necessary to specify how to measure quantities corresponding to specific operators. As far as the present

\(^9\)Let us remember here that no unbounded symmetric linear operator $A$ acting on a Hilbert space $\mathcal{H}$ can be defined on the whole space $\mathcal{H} : D(A) \nsubseteq \mathcal{H}$. \n

1.2. QUANTUM MECHANICS

author knows, this type of interpretation for arbitrary selfadjoint operators was not realized for any physical system (except, perhaps, of some systems consisting of spins only). It might be, however, sufficient to ascribe a certain empirical meaning to 'sufficiently many' operators. We can use, for such an identification of operators and empirical manipulations, the above mentioned connection between one-parameter groups of automorphisms $\tau^A$ and operators $A$. We shall take into account, moreover, that also 'microscopic systems' described adequately in the framework of quantum mechanics are only empirically specified by manipulations with 'macroscopic bodies', which are well described by CM. Let a physical system preserve its identity if the surrounding macroscopic bodies undergo some group of motions. Then we obtain a group of symmetry transformations of that system.\(^{10}\) To any one-parameter subgroup of such 'macroscopically determined' transformations corresponds in our formalism a selfadjoint operator, which in turn corresponds in some way (we shall not specify it here) to a measurable quantity connected with the macroscopic motions. We shall assume (and this is really fulfilled for many finite systems) that the group $G$ obtained in this way is large enough to determine all the 'basic observables'; all the other observables are supposed to be functions of these basic ones (see the following subsections).

1.2.7. We shall assume that a $\sigma$-continuous representation $\sigma$ of a connected Lie group $G$ in the group of $^*$-automorphisms of $L(H)$ is given and that the group $\{\sigma_g \in ^*-\text{Aut } L(H) : g \in G\}$ acts on $L(H)$ irreducibly: there is no nontrivial von Neumann subalgebra of $L(H)$ which is left invariant by the all $\sigma_g (g \in G)$. One-parameter subgroups of $G$ are in bijective correspondence with elements $\xi$ of the Lie algebra $g$ of $G$ to which, in turn, correspond selfadjoint generators $X_\xi$ of unitary groups determined by $\sigma_{\exp(\xi)}$, cf. [37, A.4.8].

Since the unitary operators $U(g)$ determined by automorphisms $\sigma_g (g \in G)$ via the relation

$$U(g)^*BU(g) = \sigma_g(B), \quad \forall B \in L(H) \quad (1.2.5)$$

are only defined up to a phase factor, in general case, the representation $\sigma$ leads only to a projective representation $g \mapsto U(g)$ of $G$ in the unitary group of $H$, i.e.

$$U(g_1g_2) = m(g_1, g_2)U(g_1)U(g_2), \quad (1.2.6)$$

where $m : G \times G \mapsto S^1$ (:= the complex numbers of unit modulus) is a multiplier of the projective representation, cf. [37, 3.3.6]. Such a representation can be always extended to a unitary representation of a group $G_m$, which is the central extension of $G$ [174, 15.2, Thm. 1] by the multiplicative group $S^1$ corresponding to the multiplier $m$, [37, 1.5-c]. The group multiplication in $G_m$ (which can be identified, as a set, with $G \times S^1$) is

$$(g_1; \lambda_1)(g_2; \lambda_2) = (g_1g_2; m(g_1, g_2)\lambda_1\lambda_2), \quad \lambda_j \in S^1. \quad (1.2.7)$$

In the unitary extension of the projective representation $U(G)$ the elements of the center of $G_m$ are represented by the numbers from $S^1$ ('phase factors') acting by multiplication of

\(^{10}\)This is so called "passive symmetry transformation", contrasted to the "active" one, when the 'physical system' is moved in the fixed environment; these two ways of understanding of transformations applied to a system are mathematically equivalent.
the vectors \( x \in \mathcal{H} \). All the extensions \( G_m \) of \( G \) (corresponding to various multipliers \( m \)) are classified by the second cohomology group \( H^2(G, S^1) \) of the group \( G \) with values in \( S^1 \), for details see [174, 321]. We shall assume that the unitary representation \( U(G_m) \) corresponding to the representation \( \sigma \) of \( G \) according to (1.2.5) can be (and really is) chosen strongly continuous. In the following we shall usually write \( G \) instead of \( G_m \).

A natural consequence of irreducibility of \( \sigma \) is the irreducibility of corresponding unitary representation \( U \). Hence, the weak-operator closure of the linear hull of the subset \( \{ U(g) : g \in G \} \) of \( \mathcal{L}(\mathcal{H}) \) in the von Neumann algebra \( \mathcal{L}(\mathcal{H}) \) is \( \mathcal{L}(\mathcal{H}) \) itself.

1.2.8. The interpretation of \( G \) as a group of (empirically defined) physical symmetries of the system leads to a natural interpretation of generators \( X_\xi (\xi \in G) \) of the unitary representation \( U \). Since any bounded operator is weakly approximated by linear combinations \( \sum \lambda_j U(g_j) \) we can hope to obtain some insight into possible interpretations of other operators. The complete answer to this problem of interpretation needs, probably, an analysis of possible interactions of the system under consideration with all other systems, or, at least with systems which could be used in the role of measuring instruments. The choice of \( G \) together with (eventually) some other assumptions on the physical properties of the system (e.g. the value of spin) might also determine the dimension of \( \mathcal{H} \).

The proper choice of the representation of \( G \) depends on comparison of consequences of the chosen 'interpretation \( U \)' with empirical data; this step contains, e.g. the choice of the correct value of the Planck constant, if \( G \) is the Heisenberg group (i.e. a central extension of the classical phase space \( \mathbb{R}^{2n} \) considered as the commutative group of translations).

1.2.9. It will be further assumed that the time evolution of the system is either a one-parameter subgroup of \( G \), or it is separately defined as a one-parameter \( \sigma \)-continuous subgroup \( \tau \) of the group of \( \sigma \)-automorphisms of \( \mathcal{L}(\mathcal{H}) \) \( t \mapsto \tau_t \in \sigma-\text{aut}(\mathcal{L}(\mathcal{H})) \), \( \tau_{t+u} = \tau_t \circ \tau_u \ (t, u \in \mathbb{R}) \), \( \tau_0 \) := identity. Note that for each automorphism \( \alpha \in \sigma-\text{aut}(\mathcal{L}(\mathcal{H})) \) there is some unitary \( U_\alpha \in \mathcal{L}(\mathcal{H}) \) such that for all \( A \in \mathcal{L}(\mathcal{H}) : \alpha(A) \equiv U_\alpha A U_\alpha^* \), i.e. the automorphisms of \( \mathcal{L}(\mathcal{H}) \) are inner automorphisms, cf. e.g. [274, Corollary 2.9.32].

1.3 Classical Hamiltonian mechanics

1.3.1. In this section, we shall outline the formal scheme of classical Hamiltonian mechanics (CM) parallel to the exposition of QM in the preceding section. We shall restrict our considerations to the case of systems with finite number of degrees of freedom. We shall use the language of differential geometry (for pedagogically well written course of differential geometry we refer to [111]). A technically more complicated quantum theory of systems with infinite number of degrees of freedom will be described later. For classical theory of infinite systems, i.e. classical field theory, see the corresponding monographs, or also e.g. [1, II.5.5], [7, Append.2], [37].

1.3.2. To any physical system there corresponds in CM a symplectic manifold \( (M; \Omega) \) (cf. [7, 1, 178]). \( M \) is here an (even dimensional) infinitely differentiable Hausdorff second countable connected manifold modeled by \( \mathbb{R}^{2n} \) and \( \Omega \) is a nondegenerate closed two-form on \( M \), the symplectic form, cf. also [37, A.3]. Observables in CM are represented by real-valued functions
1.3. CLASSICAL HAMILTONIAN MECHANICS

1.3.3. States in CM are probability Borel measures \( \mu \) on \( M \), which form a convex set \( \mathcal{S}_d \) with extremal points consisting of all measures concentrated at one-point sets in \( M \), i.e. of all Dirac measures on \( M \). Hence, pure states are identified with points \( x \in M \). Any measure \( \mu \in \mathcal{S}_d \) has a unique decomposition into (an integral of) Dirac measures, i.e. it is a simplex, contrary to the state space of QM. This has serious consequences for different possibilities of statistical interpretations of states in CM and QM, cf. 1.2.3, also footnote 8.

1.3.4. According to CM, the disturbance of the state connected with the measurement of arbitrary observables can be made negligibly small. Because of uniqueness of the decomposition of an arbitrary state to its extremal components we can interpret any \( \mu \in \mathcal{S}_d \) as a representative of a statistical ensemble of a large number of copies of the considered system, each being in its own pure state. Repeated measurements on the state \( \mu \) have to be understood now as a repeated random choice (with probability corresponding to the probability measure \( \mu \) on \( M \)) from the ensemble of a system appearing in a pure state \( x \in M \) and measuring precise values \( f(x) \) of observables \( f \in \mathcal{F}(M) \) afterwards. For such a measurement procedure the probability of finding the value of an observable \( f \) in a Borel set \( B \subset \mathbb{R} \) is \( \mu(E_f(B)) \) (compare Remark in 1.3.2), where \( \mu(f) \) for \( f \in \mathfrak{B}(M) \) means the integral of \( f \) with the measure \( \mu \) on \( M \). The value \( \mu(f) \) for \( f \in \mathcal{F}(M) \) is then the expectation value of \( f \) in the state \( \mu \in \mathcal{S}_d \). The mapping \( \mu : f \mapsto \mu(f) \) is a positive normalized linear functional on \( \mathcal{F}(M) \) (and also on \( \mathfrak{B}(M) \)), which is continuous with respect to the usual sup-norm on \( \mathfrak{B}(M) \). Better continuity properties have, e.g. functionals \( \mu \) which are absolutely continuous (as measures) with respect to the natural measure \( \Omega^n \) on the symplectic manifold \( (M; \Omega) \).

1.3.5. A symmetry of a system in CM is defined as a symplectomorphism \( F \) of \( (M; \Omega) \), i.e. \( F \) is such a diffeomorphism of \( M \) onto itself which leaves the symplectic form \( \Omega \) unchanged: \( F^*\Omega = \Omega \), where \( F^* \) is the pull-back on \( M \), see e.g. [1], or also [37, A]. For \( f \in \mathfrak{F}(M) \) let \( F^*f := f \circ F \); such an action of \( F \) onto the algebra \( \mathfrak{F}(M) \) is an automorphism. It conserves, moreover, another structure on \( \mathfrak{F}(M) \) - the Poisson algebra structure defined below.
Let $t \mapsto F_t$ be a one-parameter group of symmetries, which is differentiable with respect to $t \in \mathbb{R}: F_{t+s} = F_t \circ F_s \ (t,s, \in \mathbb{R})$ and the derivative

$$\left. \frac{d}{dt} \right|_{t=0} f(F_t x) =: d_x f(\sigma_F)$$

exists for all $f \in \mathcal{F}(M), \forall x \in M$, and the functions

$$d_f(\sigma_F) : x \mapsto d_x f(\sigma_F) \ (\in \mathbb{R})$$

are infinitely differentiable, $d_f(\sigma_F) \in \mathcal{F}(M)$. Here $\sigma_F$ is the vector field on $M$ corresponding to the flow $x \mapsto F_t x, \ (x \in M)$. Let $\mathfrak{X}(M)$ be the set of all infinitely differentiable vector fields on $M$. Let $i(\sigma) \Omega$ be the one-form on $M$ defined by: $i(\sigma) \Omega(\varphi) := \Omega(\sigma, \varphi)$ for any $\sigma, \varphi \in \mathfrak{X}(M)$, i.e. $i(\sigma) \Omega$ is the inner product [37, A.3.10] of the vector field $\sigma$ with the two-form $\Omega$. For the vector field $\sigma_F$ we have:

$$di(\sigma_F) \Omega = 0.$$  \hfill (1.3.3)

Vector fields $\sigma_F$ and the corresponding flows of symplectomorphisms $F_t$ are called locally Hamiltonian. If there is $f_F \in \mathcal{F}(M)$ such that

$$i(\sigma_F) \Omega = -df_F \text{ on } M,$$  \hfill (1.3.4)

then $\sigma_F$ is (globally) Hamiltonian and $f_F$ is its Hamiltonian function. To any $f \in \mathcal{F}(M)$, we can unambiguously define a Hamiltonian vector field $\sigma_f$ with the Hamiltonian function $f$ by the formula

$$i(\sigma_f) \Omega = -df.$$  \hfill (1.3.5)

Uniqueness of $\sigma_f$ is a consequence of nondegeneracy of $\Omega$. Two functions $f, g \in \mathcal{F}(M)$ give the same vector field $\sigma_f = \sigma_g$ iff $f - g = \text{const.}$ We can introduce now a Lie algebra structure into $\mathcal{F}(M)$, the structure of Poisson bracket multiplication: $(f; g) \mapsto \{f, g\} \in \mathcal{F}(M)$ for all $f, g \in \mathcal{F}(M)$. We define

$$\{f, g\} := \Omega(\sigma_f, \sigma_g),$$  \hfill (1.3.6)

where $\sigma_f$ (resp.$\sigma_g$) is given in (1.3.5). If we denote by $\mathcal{L}_\sigma, \sigma \in \mathfrak{X}(M)$, the Lie derivative [37, A.3.7,A.3.8] in the direction of $\sigma$ of tensor fields on $M \ (\mathcal{L}_\sigma$ acting on the differential forms has the expression $\mathcal{L}_\sigma = i(\sigma)d + di(\sigma)$), then, according to (1.3.5):

$$\{f, g\} = \mathcal{L}_{\sigma_f} g = -\mathcal{L}_{\sigma_g} f.$$  \hfill (1.3.7)

The properties of $\Omega$ are reflected in the following properties of the Poisson bracket:
are defined globally on the manifold $M$, $f$ will be linear. Then $f$ constants in the definitions of Hamiltonian. We shall assume that this is the case for our $(M, \Omega)$. Then arbitrary additive constants in the definitions of $f$'s can be chosen such that the mapping $\xi \mapsto f_\xi$ from $\mathfrak{g}$ to $\mathfrak{X}(M)$ will be linear. Then

$$\{f_\xi, f_\eta\} = -f_{[\xi, \eta]} + C(\xi, \eta),$$

(1.3.11)

\[ \{ f, g \} = \{ f, g \} + \lambda \{ f, h \}, \]

(1.3.8)

1.3.6. In CM, all the observables are functions of points $x \in M$, hence locally can be expressed as functions of a finite number $2n$ coordinate functions. In accordance with the 'philosophy' of 1.2.6, we shall look for an interpretation of a finite number of observables which contain systems of coordinate functions for a neighbourhood of any point of $M$. This can be naturally done, if $M$ is a homogeneous space of a connected Lie group $G$ (cf. [37, A.4]) corresponding to a group of empirical manipulations with objects relevant to the determination of the considered system. Since the symplectic structure $\Omega$ on $M$ reflects important physical properties of many physical systems, it is desirable for the group action on $M$ to conserve this structure. In this case, one parameter subgroups of symmetries correspond to Hamiltonian flows which can be physically interpreted.

1.3.7. From now on, we shall assume that $(M; \Omega)$ is a homogeneous space of a connected Lie group $G$, on which the group $G$ acts as an infinitely differentiable group of symplectomorphisms $F_g$ ($g \in G$): $F_g^* \Omega = \Omega$, $F_{gh} = F_g \circ F_h$ ($g, h, \in G$), and functions $g \mapsto f(F_g x)$ are in $C^\infty(G, \mathbb{R})$ for all $f \in \mathfrak{X}(M)$ and all $x \in M$. If $e \in G$ is the unit element of $G$, then $F_e := id_M$. To any $\xi \in \mathfrak{g}$ ($:= \text{the Lie algebra of } G$) there is a one-parameter group of symplectomorphisms $t \mapsto f_{\exp(t\xi)}$ of $M$ generated by the vector field $\sigma_\xi$ (compare with (1.3.1)). If $[\xi, \eta]$ denotes the \textbf{commutator in} $\mathfrak{g}$, and $[\sigma_\xi, \sigma_\eta] \in \mathfrak{X}(M)$ the \textbf{commutator of vector fields} on $M$, then (see [1, Proposition 4.1.26])

$$[\sigma_\xi, \sigma_\eta] = -\sigma_{[\xi, \eta]}.$$  

(1.3.9)

Every homogeneous symplectic manifold has universal covering symplectic homogeneous manifold with respect to the universal covering group of $G$. On any simply connected homogeneous symplectic manifold of a connected Lie group $G$, the functions $f_\xi$ ($\xi \in \mathfrak{g}$) determined up to additive constants by the formula

$$i(\sigma_\xi)\Omega = -df_\xi$$

(1.3.10)

are defined globally on the manifold $M$, $f_\xi \in \mathfrak{X}(M)$, i.e. the vector fields $\sigma_\xi$ ($\xi \in \mathfrak{g}$) are globally Hamiltonian. We shall assume that this is the case for our $(M, \Omega)$. Then arbitrary additive constants in the definitions of $f_\xi$'s can be chosen such that the mapping $\xi \mapsto f_\xi$ from $\mathfrak{g}$ to $\mathfrak{X}(M)$ will be linear. Then

$$\{ f_\xi, f_\eta \} = -f_{[\xi, \eta]} + C(\xi, \eta),$$

(1.3.11)
CHAPTER 1. INTRODUCTION

where $C$ is a bilinear antisymmetric mapping from $\mathfrak{g} \times \mathfrak{g}$ to real constants on $M$ called a two-cocycle on $\mathfrak{g}$ with values in $\mathbb{R}$. Any change of constants in $f_\xi$'s (conserving the linearity of $\xi \mapsto f_\xi$) leads to an equivalent cocycle $C'(\xi, \eta) = C(\xi, \eta) + a([\xi, \eta])$, where $a \in \mathfrak{g}^*$ (:= the dual of $\mathfrak{g}$). Equivalence classes of two-cocycles form the commutative (additive) 

2-cohomology group $H^2(\mathfrak{g}, \mathbb{R})$ 

of $\mathfrak{g}$ with values in $\mathbb{R}$. This group is isomorphic to $H^2(G, S^1)$ if $G$ is simply connected (compare [321, Chap. 10.4.]). This isomorphism determines a canonical bijection between classes of irreducible projective representations and symplectic transitive actions of a simply connected Lie group. This bijection associates the class of all representations corresponding to the given (similarity class of a) multiplier with the class of symplectic actions with the corresponding (equivalence class of a) cocycle, compare also [28, 139]. If the multiplier $m$ corresponds to the cocycle $C$ from (1.3.11), then the central extension $G_m$ of $G$ (cf. [174, 15.2, Thm. 1]) acts on $M$ in such a way, that

$$\{f_\xi, f_\eta\} = -f_{[\xi, \eta]} \quad \text{for all } \xi, \eta \in \mathfrak{g}_m, \quad (1.3.12)$$

if the added vector fields act on $M$ trivially and constants in $f_\xi$'s are properly chosen. If the action of $G$ on $M$ satisfies (1.3.11) with $C \equiv 0$, then it is called a Poisson action [7], and the symplectic manifold $M$ is called exactly homogeneous [174].

1.3.8. Any observable $f \in \mathfrak{g}(M)$ on the homogeneous symplectic manifold $M$ with globally defined Hamiltonian functions $f_\xi (\xi \in \mathfrak{g})$ can be expressed as a function of the 'basic observables $f_\xi$'.' Hence measurement of any $f \in \mathfrak{g}(M)$ can be reduced to the measurements of $f_\xi$'s. This does not make easier, however, of an ascribing a direct physical (i.e. empirical) interpretation to an arbitrary $f \in \mathfrak{g}(M)$ and the situation is similar to that one of QM, see 1.2.8.

1.3.9. A time evolution on $(M; \Omega)$ is defined in CM as a differentiable one-parameter group of symplectomorphisms with a globally defined Hamiltonian function $h \in \mathfrak{g}(M)$. This one-parameter group might be either a subgroup of $G$, or it is separately defined. In each case the group $G$ might contain an invariance subgroup of $h$ - the symmetry group of the dynamics (determining integrals of motion - conservation laws).

1.4 Quantum theory of large systems

1.4.1. Models of systems with infinite number of degrees of freedom enter to quantum theory when we want to describe either processes accompanied with changes of numbers of particles (resp. quasiparticles) present in the physical system (what also occurs each time if we try to describe quantal analogues of classical continuous media, resp. fields), or systems with actual infinity of particles (the 'thermodynamic limit' necessary e.g. for clear conceptual description and abstract investigation of phase transitions). In standard models of infinite systems in quantum theory the algebras of bounded observables (e.g, CCR or CAR algebras for infinite number
of degrees of freedom or algebras of spin systems on infinite lattices) have many mutually unitarily inequivalent physically relevant representations as algebras of bounded operators in some Hilbert spaces. These inequivalent representations might correspond e.g. to various states on the algebra of observables representing situations with various values of some macroscopic–global parameters of the large system. It often happens, moreover, that for description of some processes (time evolution, symmetry transformations), we are not able to work in the framework of only one (even faithful) representation. It is, consequently, useful to formulate theoretical scheme for the quantum theory of large systems (QTLS) in a representation independent, algebraic language. As basic sources of most of the here necessary mathematics and its application to description of large quantal systems could be taken, e.g. [53, 54, 84, 235, 223, 274, 286, 289]; a very brief summary can be found also in [37, Sec.3.4].

1.4.2. A $C^*$-algebra $\mathfrak{A}$ [37, B.2] (details on $C^*$-algebras can be found in [90, 91, 274, 275, 235, 305, 306, 53, 54, 106]) corresponds to any physical system in QTLS. $\mathfrak{A}$ is a Banach algebra over complex numbers with involution $x \mapsto x^*$, $x \in \mathfrak{A}$, and with special ($C^*$) property. This means that it is a norm-closed linear space endowed with associative and distributive multiplication, and for any $x, y \in \mathfrak{A}$, $\lambda \in \mathbb{C}$, and with $\|x\| \geq 0$ - the norm of $x \in \mathfrak{A}$, it is: $\|xy\| \leq \|x\| \cdot \|y\|$, the involution $x \mapsto x^*$ is antilinear: $(x + \lambda y)^* = x^* + \bar{\lambda} y^*$, where $\bar{\lambda}$ is the complex conjugate of $\lambda$, with $(xy)^* = y^* x^*$, $\|x^*\| = \|x\| (= 0 \text{ iff } x = 0)$, and the $C^*$-property means: $\|x^* x\| = \|x\|^2$, $\forall x \in \mathfrak{A}$. $\mathfrak{A}$ is called unital $C^*$-algebra if it contains unit element $e \in \mathfrak{A}$: $ex = xe = x$, $\forall x \in \mathfrak{A}$. Selfadjoint elements $x = x^* \in \mathfrak{A}$ represent bounded observables of the system. The algebra $\mathfrak{A}$ is the algebra of observables of the system. For many interesting systems, $\mathfrak{A}$ is constructed as a $C^*$-inductive limit of a net of local algebras of finite (sub)systems (see [53, 106, 274], and specifically [274, 1.23]); in this case, these finite systems are interpreted e.g. as systems located in bounded space (-time) regions. Quasilocal algebras used in QTLS have such a structure (see [53, Definition 2.6.3]). It will be useful in our considerations to connect the quasilocal structure of $\mathfrak{A}$ with an action of a (usually abelian) group $\Pi$ (\Pi is an infinite set - it might be a locally compact noncompact group) on $\mathfrak{A}$: For any $p \in \Pi$ let $\pi(p) \in Aut \mathfrak{A}$, $\pi(p_1 p_2) = \pi(p_1) \pi(p_2)$ ($p_1, p_2 \in \Pi$). Let $\Pi$ act transitively on a noncompact locally compact space $V$ and let to any bounded open subset $v \subset V$ (denote the set of all such subsets by $B(V)$) corresponds a $C^*$-subalgebra $\mathfrak{A}_v$ of $\mathfrak{A}$, the local subalgebra of $\mathfrak{A}$ corresponding to $v \subset V$. If $v_1 \subset v_2 \subset V$, then $\mathfrak{A}_{v_1} \subset \mathfrak{A}_{v_2}$. All the $\mathfrak{A}_v$ ($v \in B(V)$) have common unit $\equiv$ the unit $e := id_\mathfrak{A}$ of $\mathfrak{A}$, and

$$
\bigcup_{v \in B(V)} \mathfrak{A}_v = \mathfrak{A},
$$

where the over-bar denotes the uniform closure. We assume further that $\pi(p)(\mathfrak{A}_v) = \mathfrak{A}_{p \cdot v}$, where $p \cdot v := \{\lambda' \in V : \lambda' = p \cdot \lambda, \lambda \in v\}$, and $p \cdot \lambda$ denotes the action of $p \in \Pi$ on the point $\lambda \in V$. This action is supposed continuous and bounded: $p \cdot B(V) \subset B(V)$ for all $p \in \Pi$. We can assume (for simplicity) that for mutually disjoint $v, u \in B(V)$, $v \cap u = \emptyset$, we have

$$
[x, y] = 0, \text{ for all } x \in \mathfrak{A}_v, y \in \mathfrak{A}_u.
$$

(1.4.2)
(The anticommutativity of Fermi systems can also be included, cf. [53, Sec. 2.6]). We shall characterize this situation by saying that the algebra $\mathcal{A}$ is quasilocal with respect to the action of the group $\Pi$. We shall use another technical assumption, that all the local subalgebras $\mathcal{A}_v$ are $W^*$-algebras: A $W^*$-algebra $\mathcal{A}$ is such a $C^*$-algebra which is (isomorphic to a) Banach space topological dual of another B-space $\mathcal{A}$, called the predual of $\mathcal{A}$; such an $\mathcal{A}$ is always unital and generated by its projectors. $W^*$-algebras were introduced originally as weakly closed symmetric subalgebras of bounded operators in a Hilbert space containing identity and named von Neumann algebras after their originator.

1.4.3. Mathematically defined states on a $C^*$-algebra $\mathcal{A}$ are any positive normalized linear functionals $\omega$ on $\mathcal{A}$, i.e. such $\omega \in \mathcal{A}^* (:= \text{the dual of } \mathcal{A})$, that

$$\omega(x^*x) \geq 0, \quad \|\omega\| = 1 \quad (= \omega(id_{\mathcal{A}})).$$

(1.4.3)

Not all mathematical states, however, can be used as adequate descriptions of physical situations. As physical states on a quasilocal algebra $\mathcal{A}$ are usually used locally normal states, i.e. such states $\omega$ on $\mathcal{A}$, the restrictions of which to all the local $W^*$-subalgebras $\mathcal{A}_v \ (v \in B(V))$ are $\sigma(\mathcal{A}_v, (\mathcal{A}_v)_*)$-continuous (here $(\mathcal{A}_v)_*$ is the predual Banach space of $\mathcal{A}_v$); the local normality of $\omega$ means that the restriction of $\omega$ to any $\mathcal{A}_v$ is expressible by a density matrix in a faithful $W^*$-representation of $\mathcal{A}_v$. We shall denote by $\mathcal{S}(\mathcal{A})$ the set of all mathematical states on $\mathcal{A}$ and by $\mathcal{S}_{ph} := \mathcal{S}_{ph}(\mathcal{A})$ the set of (properly defined) physical states of the system. The subset $\mathcal{S}_{ph}(\mathcal{A}) \subset \mathcal{S}(\mathcal{A})$ has to satisfy some natural requirements, e.g. invariance with respect to transformations of physical symmetries (cf. below), convexity, local normality and (eventually) to form a stable face (see [53, Sec.4.1]).

The set $\mathcal{S}(\mathcal{A})$ is convex and compact in the $w^*$-topology of $\mathcal{A}^*$ (i.e. in $\sigma(\mathcal{A}^*, \mathcal{A}^*)$-topology). The set $\mathcal{E}\mathcal{S}(\mathcal{A})$ of extreme points of $\mathcal{S}(\mathcal{A})$ consists of pure states on $\mathcal{A}$: $\omega \in \mathcal{E}\mathcal{S}(\mathcal{A}) \Leftrightarrow \{\omega = \frac{1}{2}\omega_1 + \frac{1}{2}\omega_2 \ (\omega_{1,2} \in \mathcal{S}(\mathcal{A})) \Rightarrow \omega_1 = \omega_2 = \omega\}$. Although the decomposition of a general $\omega \in \mathcal{S}(\mathcal{A})$ into its extremal components (in $\mathcal{E}\mathcal{S}(\mathcal{A})$) is not unique if $\mathcal{A}$ is noncommutative, there are other physically relevant convex compact subsets of $\mathcal{S}(\mathcal{A})$ (Choquet simplexes) allowing unique extremal decompositions of their elements into extremal components of these simplexes, cf. [73, 218] for basic mathematics, or also [53, Ch.4], [235, Ch.4], [274, Ch.3] for broader contexts.

1.4.4. The expectation value of a bounded observable $x = x^* \in \mathcal{A}$ in the state $\omega \in \mathcal{S}(\mathcal{A})$ (in accordance with comments in 1.2.4) is expressed by the value $\omega(x)$ of the functional $\omega$ on the element $x$. For calculations of probability distributions of values of $x = x^* \in \mathcal{A}$ in the states $\omega \in \mathcal{S}(\mathcal{A})$ it is used, however, the spectral decomposition of $x$. If $\mathcal{A}$ is a general $C^*$-algebra, its selfadjoint elements need not have their spectral resolutions in $\mathcal{A}$. The spectral resolutions in $\mathcal{A}$ exist, however, if $\mathcal{A}$ is a $W^*$-algebra, [274]: $x = x^* \in \mathcal{A} \Rightarrow x = \int_{\mathbb{R}} \lambda E_x(d\lambda), \ E_x(B)^* = E_x(B) = E_x(B)^2 \in \mathcal{A}, \ B \subset \mathbb{R} \text{ Borel}, \ldots$, hence $E_x$ is the projector valued spectral measure in the $W^*$-algebra $\mathcal{A}$. Any $C^*$-algebra is naturally embedded into a $W^*$-algebra - the bidual

\footnote{Our formalism is built for the nonrelativistic situations. If the space $V$ was the Minkowski space and our considerations were Einstein-Lorentz–relativistic, the condition for the commutativity in (1.4.2) would be the space–like separation instead of the disjointness of the domains $u, v \subset V$.}
of $\mathfrak{A}$, and any state $\omega \in \mathcal{S}(\mathfrak{A})$ can be uniquely extended to a state (equally denoted) $\omega \in S_c(\mathfrak{A}^{**})$. For any state $\omega \in \mathcal{S}(\mathfrak{A})$, we can construct by the GNS-algorithm corresponding cyclic representation $\pi_\omega$ of $\mathfrak{A}$ in a Hilbert space $\mathcal{H}_\omega$ with a cyclic vector $\Omega_\omega$ (i.e. the norm-closure $\pi_\omega(\mathfrak{A})\Omega_\omega = \mathcal{H}_\omega$), cf. [53, 223, 274], characterized (up to the unitary equivalence) by

$$\omega(x) = (\Omega_\omega, \pi_\omega(x)\Omega_\omega), \quad \forall x \in \mathfrak{A}. \quad (1.4.4)$$

The representation $\pi_\omega$ is irreducible iff $\omega \in \mathcal{ES}(\mathfrak{A})$. If we generalize the concept of observables to all operators from the bicommutant $\pi_\omega(\mathfrak{A})''$ in $\mathcal{L}(\mathcal{H}_\omega)$ (what is a $W^*$-subalgebra in $\mathcal{L}(\mathcal{H}_\omega)$), we can obtain spectral resolutions of selfadjoint elements of $\mathfrak{A}$ in such (extended) representations and the corresponding expressions for probability distributions, compare 1.2.4. In specific representations, we can define also unbounded observables as such selfadjoint operators on $\mathcal{H}_\omega$ the spectral projectors of which belong to $\pi_\omega(\mathfrak{A})''$, cf. [274].

We shall need later in this work to distinguish between states which are mutually macroscopically distinguishable. Mathematically are such states mutually disjoint together with the mutual disjointness of their GNS representations. It might be useful, for a characterization of this difference, to reproduce a theorem from [235, Thm. 3.8.11]:

**Theorem:** Let $\{\pi_1; \mathcal{H}_1\}$, $\{\pi_2; \mathcal{H}_2\}$ be two nondegenerate representations of a $C^*$-algebra $\mathfrak{A}$ with their central supports (equiv. central covers) $s_1$, $s_2$, cf. [235, 3.8.1]. The following conditions are equivalent:

(i) $s_1 \perp s_2$.

(ii) $((\pi_1 \oplus \pi_2)(\mathfrak{A}))'' = \pi_1(\mathfrak{A})'' \oplus \pi_2(\mathfrak{A})''$.

(iii) $((\pi_1 \oplus \pi_2)(\mathfrak{A}')) = \pi_1(\mathfrak{A}') \oplus \pi_2(\mathfrak{A})'$.

(iv) There are no unitarily equivalent subrepresentations of $\{\pi_1; \mathcal{H}_1\}$ and $\{\pi_2; \mathcal{H}_2\}$.

Here $\mathcal{C}'$ for a subset $\mathcal{C} \subset \mathcal{L}(\mathcal{H})$ denotes the commutant of $\mathcal{C}$ in $\mathcal{L}(\mathcal{H})$: $\mathcal{C}' := \{B \in \mathcal{L}(\mathcal{H}) : [B, A] \equiv BA - AB = 0, \forall A \in \mathcal{C}\}$, and $\mathcal{C}'' := (\mathcal{C}')'$. The representations $\pi_1$, $\pi_2$ satisfying the conditions of the Theorem are called mutually disjoint representations. If the GNS representations determined by the two states $\omega_1$, $\omega_2$: $\{\pi_{\omega_1}; \mathcal{H}_{\omega_1}\}$, $\{\pi_{\omega_2}; \mathcal{H}_{\omega_2}\}$, are mutually disjoint, then we call these two states also mutually disjoint: $\omega_1 \perp \omega_2$.

1.4.5. An abstractly defined symmetry of the system in QTLS is any $^*$-automorphism of the algebra $\mathfrak{A}$ of bounded observables. Let $\tau$ be a representation of the group $\mathbb{R}$ as a group of symmetries, i.e. a homomorphism $t(\in \mathbb{R}) \mapsto \tau_t \in ^* \text{Aut} \mathfrak{A}$, which is 'conveniently continuous', e.g. functions $t \mapsto \omega(\tau_t x)$ are continuous for all $x \in \mathfrak{A}$ and all $\omega \in S_{ph}(\mathfrak{A})$. It is often assumed, that the group $\tau$ corresponding to a one-parameter group of empirically defined transformations is $\sigma(\mathfrak{A}, \mathfrak{A}^*)$-continuous (i.e. $S_{ph}$ replaced by $S(\mathfrak{A})$ in the last mentioned case), but this assumption might be too stringent. Let $\mathcal{S}$ be a 'sufficiently large' subset of states containing $S_{ph}$ and denote by $\sigma(\mathfrak{A}, \mathcal{S})$ the topology on $\mathfrak{A}$ determined by functions $x(\in \mathfrak{A}) \mapsto \omega(x)$ for all $\omega \in \mathcal{S}$. We shall assume, that $\tau$ is $\sigma(\mathfrak{A}, \mathcal{S})$-continuous in the sense:

(i) functions $t \mapsto \omega(\tau_t x)$ are continuous for all $\omega \in \mathcal{S}$, $x \in \mathfrak{A}$,

(ii) functions $x \mapsto \tau_t x$ are $\sigma(\mathfrak{A}, \mathcal{S}) - \sigma(\mathfrak{A}, \mathcal{S})$ - continuous for all $t \in \mathbb{R}$,

(iii) $\omega \in \mathcal{S} \Rightarrow \omega \circ \tau_t \in \mathcal{S}$ for all $t \in \mathbb{R}$. 
The last condition (iii) allows us to define a $\sigma(S,\mathfrak{A})$-continuous group of transformations of $S$ by

$$\tau_t^*\omega := \omega \circ \tau_t \quad (\text{for all } t \in \mathbb{R}), \ \omega \in S. \quad (1.4.5)$$

Any selfadjoint element $a \in \mathfrak{A}$ generates a $\sigma(\mathfrak{A},S)$ (i.e. $\sigma(\mathfrak{A},\mathfrak{A}^*)$)-continuous group of inner *-automorphisms of $\mathfrak{A}$, $\tau^a$, by

$$\tau_t^a x := \exp(ita)x\exp(-ita), \quad \text{for all } x \in \mathfrak{A}. \quad (1.4.6)$$

A one-parameter group of inner automorphisms of $\mathfrak{A}$ cannot represent some of physically important global transformations of quasilocal algebras, e.g. Euclidean or Poincaré transformations, cf. e.g. [106, Ch.4,Thm.3]. For a general (sufficiently continuous) one-parameter group $\tau$ of automorphisms of $\mathfrak{A}$ we can define a generator $\delta_\tau$ - a densely defined derivation on $\mathfrak{A}$, [274, 53].

12 A densely defined linear mapping $\delta : D(\delta) \subset \mathfrak{A} \rightarrow \mathfrak{A}$ is a derivation on $\mathfrak{A}$ if it satisfies the Leibniz rule:

$$\delta(xy) = \delta(x)y + x\delta(y) \quad \forall \ x, y \in D(\delta) \subset \mathfrak{A}.$$
Chapter 2

Geometry of the state space of quantum mechanics

2.1 Manifold structure of $P(\mathcal{H})$

2.1.1. Let $\mathcal{H}$ be a complex separable Hilbert space with the scalar product $(x, y) \in \mathbb{C}$ $(x, y, \in \mathcal{H})$, which is linear in the second factor $y$. Let $P(\mathcal{H}) := \mathcal{H}/\mathbb{C}^*$ be the factor-space of $\mathcal{H}$ by the multiplicative group $\mathbb{C}^*$ of nonzero complex numbers acting on $\mathcal{H}$ by multiplications by scalars. Any element $x \in P(\mathcal{H})$ has the form

\[ x := \{ y \in \mathcal{H} : y = \lambda x, \lambda \in \mathbb{C}^* \}, \quad 0 \neq x \in \mathcal{H}. \]  

(2.1.1)

The natural topology on $P(\mathcal{H})$ is the factor-topology coming from the norm-topology in $\mathcal{H}$. This topological space $P(\mathcal{H})$ is the projective Hilbert space of $\mathcal{H}$. The space $P(\mathcal{H})$ can be considered as the set of all one-dimensional complex subspaces of $\mathcal{H}$, or the set of all one-dimensional projectors $P_x \in \mathcal{L}(\mathcal{H})$ $(0 \neq x \in \mathcal{H})$, $P_x^* = P_x = P_x^2$, $P_x x = x$, with the natural bijective correspondence $P_x \leftrightarrow x$. It is known that there is a natural Kähler structure on complex projective spaces. We shall describe it in some details in the case of $P(\mathcal{H})$.

2.1.2. Let us define two natural (mutually equivalent) metrices (i.e. distance functions) $d_1, d_2$ on $P(\mathcal{H})$ (as usual: $\|x\|^2 := (x, x), \quad x \in \mathcal{H}$):

\[ d_1(x, y) := \sqrt{2} \inf \{ \frac{x}{\|x\|} - e^{i\lambda} \frac{y}{\|y\|} : \lambda \in \mathbb{R} \}, \]  

(2.1.2)

\[ d_2(x, y) := \sqrt{2} \| P_x - P_y \|. \]  

(2.1.3)

It is not difficult to see that

\[ d_1(x, y) = 2 \left( 1 - (Tr(P_x P_y))^{1/2} \right)^{1/2}. \]  

(2.1.4)

1Another, more intuitive and more detailed approach to the structure of quantum state space can be found in [16]. For geometry and dynamics (also nonlinear) of general - not only pure - states see also [37, Sec.2.1].
In (2.1.3), \(\|A\|\) denotes the usual \(C^*\)-norm of the operator \(A \in \mathcal{L}(\mathcal{H})\); if \(|A| := \sqrt{A^*A} \in \mathcal{L}(\mathcal{H})\) is its absolute value, then one can prove

\[
\sqrt{2}d_2(x, y) = Tr|P_x - P_y| = 2(1 - Tr(P_xP_y))^{1/2},
\]

\[
= (1 + (Tr(P_xP_y))^{1/2})^{1/2} d_1(x, y),
\]

what proves the equivalence of \(d_1\) and \(d_2\).

We shall examine now relations between various natural topologies on \(P(\mathcal{H})\). We shall prove first

**2.1.3 Lemma.** The factor-topology on \(P(\mathcal{H})\) coming from the Hilbert-space norm-topology of \(\mathcal{H}\) is equivalent to the metric topology defined on \(P(\mathcal{H})\) by the distance function \(d_1\) (equiv.: by \(d_2\)).

**Proof.** Let \(Pr: x \mapsto x\) be the natural projection of \(\mathcal{H}\) onto \(P(\mathcal{H})\). The factor-topology on \(P(\mathcal{H})\) is generated by projections of open balls \(B(x; \varepsilon) := \{y \in \mathcal{H}: \|x - y\| < \varepsilon\}\) for \(\varepsilon > 0\), \(x \neq 0\). But \(Pr B(x; \varepsilon) = \{y \in P(\mathcal{H}) : \inf\{\|\lambda y - x\| : \lambda \in \mathbb{C}\} < \varepsilon\}\), and \(\inf\{\|\lambda y - x\| : \lambda \in \mathbb{C}\} = \|z_y - x\|\) with \(z_y := \frac{\langle x, y \rangle}{\|y\|^2}y\) if \(y \neq 0\). Hence \(Pr B(x; \varepsilon) = \{y : \|z_y - x\| < \varepsilon\} = \{y : 1 - Tr(P_xP_y) < \frac{\varepsilon}{\|x\|^2}\} = \{y \in P(\mathcal{H}) : d_2(x, y) < \sqrt{2 \frac{\varepsilon}{\|x\|^2}}\}\), which is an open ball in the metric topology and the desired equivalence of topologies follows.

**2.1.4 Proposition.** All the following natural topologies on \(P(\mathcal{H})\) are mutually equivalent:

(i) the factor-topology coming from the Hilbert-space norm-topology on \(\mathcal{H}\);

(ii) the metric topology defined by the distance functions on \(P(\mathcal{H})\) from 2.1.2;

(iii) the Hilbert-Schmidt topology of \(\mathcal{H} \subset \mathcal{L}(\mathcal{H})\) of Hilbert-Schmidt operators;

(iv) the trace-norm topology of \(\mathfrak{T}(\mathcal{H})\);

(v) \(\sigma(P(\mathcal{H}), \mathcal{L}(\mathcal{H}))\)-topology;

(vi) \(\sigma(P(\mathcal{H}), \mathfrak{C}(\mathcal{H}))\)-topology.

[In (v), resp. (vi), the topologies are determined by the functions \(x \mapsto Tr(P_xA)\) for all \(A \in \mathcal{L}(\mathcal{H})\), resp. for all \(A \in \mathfrak{C}(\mathcal{H}) := \text{the set of all compact operators on } \mathcal{H}\).]

**Proof.** The equivalence of the first four topologies follows from the lemma 2.1.3 and from the formulas (2.1.3), (2.1.5), since the Hilbert-Schmidt operator topology is given by the norm

\[
\|P_x - P_y\|_{HS} := Tr(P_x - P_y)^2 = 2(1 - Tr(P_xP_y)) = [d_2(x, y)]^2.
\]

The equivalence of the trace-norm topology and the \(\sigma(P(\mathcal{H}), \mathfrak{C}(\mathcal{H}))\)-topology follows from [53, Proposition 2.16.15], and the ‘stronger’ \(\sigma(P(\mathcal{H}), \mathcal{L}(\mathcal{H}))\)-topology coincides with the \(w^*\)-topology from \(\mathcal{L}(\mathcal{H})^*\), which is ‘weaker’ than the norm-topology of \(\mathcal{L}(\mathcal{H})^*\). The last mentioned topology coincides on \(P(\mathcal{H})\) with the trace-norm topology given by the metric \(d_2(x, y) \propto Tr|P_x - P_y|\), what finishes the proof. \(\square\)
2.1.5. We shall introduce now a manifold structure on \( P(\mathcal{H}) \) consistent with the topology of \( P(\mathcal{H}) \). Let for \( 0 \neq x \in \mathcal{H} \)

\[
N_x := \{ y \in P(\mathcal{H}) : \text{Tr}(P_x P_y) \neq 0 \}
\]

be an open *neighbourhood of* \( x \in P(\mathcal{H}) \), and let \( [x]^{\perp} \) be the complex orthogonal complement of \( x \) in \( \mathcal{H} \). We shall define the mapping \( \Psi_x : N_x \mapsto [x]^{\perp} \) by the formula

\[
\Psi_x(y) := \frac{\|x\|^2}{(x, y)} (I - P_x)y,
\]

where \( y \in y \).

2.1.6 Proposition. The mapping \( \Psi_x \) is a homeomorphism of \( N_x \) onto \([x]^{\perp} \) (with the norm-topology of \( \mathcal{H} \)). The set

\[
\{ (N_x ; \Psi_x ; [x]^{\perp}) : 0 \neq x \in \mathcal{H} \}
\]

is an atlas on \( P(\mathcal{H}) \) defining a complex-analytic manifold structure consistent with the topology of \( P(\mathcal{H}) \) (defined in 2.1.1).

Proof. Let \( 0 \neq x \in \mathcal{H} \). For any \( y_j \in N_x \) and any \( y_j \in y_j \) (\( j = 1, 2 \)) it is \( y_1 \neq y_2 \) iff \( (x, y_2)y_1 \neq (x, y_1)y_2 \), hence \( \Psi_x \) is injective. For any \( z \in [x]^{\perp} \) and \( y := z + x \) we have \( y \in N_x \) (since \( x \neq 0 \)) and \( \Psi_x(y) = z \), hence \( \Psi_x \) is bijective. For \( \|x\| = 1 \) and \( z_j \in [x]^{\perp} \), \( y_j := z_j + x \) (\( j = 1, 2 \)) the identity

\[
1 - \text{Tr}(P_{y_1} P_{y_2}) = \frac{1}{(\|z_1\|^2 + 1)(\|z_2\|^2 + 1)} (\|z_1 - z_2\|^2 + \|z_2\|^2 + (1 - P_{z_2})(z_1 - z_2))^2)
\]

implies the bicontinuity of \( \Psi_x \). For \( z \in \Psi_{x_1}(N_{x_1} \cap N_{x_2}) \) it is

\[
\Psi_{x_2} \circ \Psi_{x_1}^{-1}(z) = \|x_2\|^2 \frac{x_1 + z}{(x_2, x_1 + z)} - x_2
\]

and we see that the mapping

\[
\Psi_{x_2} \circ \Psi_{x_1}^{-1} : \Psi_{x_1}(N_{x_1} \cap N_{x_2}) \to \Psi_{x_2}(N_{x_1} \cap N_{x_2})
\]

is a complex analytic function, compare e.g. [51, 71]. \( \square \)

2.1.7. Let \( T_x P(\mathcal{H}) \) be the **tangent space of** \( P(\mathcal{H}) \) **at** \( x \), elements of which can be represented in the usual way (see e.g. [1, 74]) by (classes of mutually tangent) differentiable curves at \( x \). If \( c \) is such a curve (i.e. \( c : J \to P(\mathcal{H}) \) for an open interval \( J \) in \( \mathbb{R} \) containing \( 0 \in \mathbb{R} \), \( c(0) = x \) and \( t \mapsto \Psi_y(c(t)) \) is differentiable for \( x \in N_y \) denote by \( \dot{c}_x := \dot{c}(0) \) (or simply \( \dot{c} \) if the point \( x \) is fixed) the corresponding equivalence class, \( \dot{c}_x \in T_x P(\mathcal{H}) \). With any \( x \in x \), we associate an identification of \( T_x P(\mathcal{H}) \) with \([x]^{\perp} \) by the mapping

\[
T_x \Psi_x : T_x P(\mathcal{H}) \to [x]^{\perp}, \; \dot{c} \mapsto T_x \Psi_x(\dot{c}) := \frac{d}{dt} \bigg|_{t=0} \Psi_x(c(t)).
\]
In (2.1.12), we identify, in the usual way, the tangent space \( T_x[x]^\perp \) of the linear space \( [x]^\perp \) at any of its points \( v \in [x]^\perp \) with the base space \( [x]^\perp \) itself. The mapping \( T_x \Psi_x \) is a linear isomorphism for any \( x \in \mathfrak{x} \), and also \( T_x \Psi_{x x} = \lambda T_x \Psi_x \) (\( \lambda \in \mathbb{C} \)). The derivative in (2.1.12) is taken with respect to the Hilbert space norm in \( [x]^\perp \).

2.1.8. Let us mention two simple examples of the representation of elements \( \dot{c} \in T_x P(\mathcal{H}) \) by curves \( c \) and of the corresponding identification of \( T_x P(\mathcal{H}) \) with \( [x]^\perp \). Each vector \( \dot{c} \in T_x P(\mathcal{H}) \) can be represented by a curve of any of the following forms (the expressions written by bold typeface represent the projections to \( P(\mathcal{H}) \) of the corresponding elements of \( \mathcal{H} \), i.e. \( z(\in \mathcal{H}) \mapsto z \equiv P_z(\in P(\mathcal{H})) \):

\[
\begin{align*}
c_1(t) &:= \lambda x + ty \equiv P_{\lambda x + ty} \quad (\lambda \in \mathbb{C}, \, y \in \mathcal{H}, \, x \in \mathfrak{x}), \quad t \in \mathbb{R}, \tag{2.1.13} \\
c_2(t) &:= \exp(itB)x \equiv P_{\exp(itB)x} \quad (B = B^* \in \mathcal{L}(\mathcal{H}), \, x \in \mathfrak{x}), \quad t \in \mathbb{R}. \tag{2.1.14}
\end{align*}
\]

If we denote corresponding tangent vectors by \( \dot{c}_1 \) and \( \dot{c}_2 \), then

\[
\begin{align*}
T_x \Psi_x(\dot{c}_1) &= \lambda^{-1}(1 - P_x)y, \tag{2.1.15} \\
T_x \Psi_x(\dot{c}_2) &= i(1 - P_x)Bx. \tag{2.1.16}
\end{align*}
\]

Clearly \( \dot{c}_1 = \dot{c}_2 \) iff the right hand sides of (2.1.15) and (2.1.16) coincide as vectors in \( [x]^\perp \). This is the case if e.g. \( y = i\lambda Bx \) in (2.1.15). The representants \( (c_1, \text{ or } c_2, \text{ or } \ldots) \) of a given \( \dot{c} \) can be chosen in many various ways. We shall use notation:

\[
v_x := T_x \Psi_x(v) \in [x]^\perp
\]

for \( v \in T_x P(\mathcal{H}) \); \( v_{\lambda x} = \lambda v_x \).

2.1.9. We shall consider \( P(\mathcal{H}) \) as a \textbf{real manifold} of the dimension \( \dim P(\mathcal{H}) = 2 \dim_{\mathbb{C}} \mathcal{H} - 2 \), (if \( \mathcal{H} \) is finite dimensional) where \( \dim_{\mathbb{C}} \) means the complex dimension. On this manifold, we introduce a \textbf{metric} \( Q \), i.e. a real-analytic symmetric 2-covariant tensor field \( \mathfrak{x} \mapsto Q_\mathfrak{x} \) defining an isomorphism between \( T_x P(\mathcal{H}) \) and its dual \( T^*_x P(\mathcal{H}) \) at any point \( x \in P(\mathcal{H}) \):

\[
v \in T_x P(\mathcal{H}) \mapsto Q_\mathfrak{x}(v, \cdot) \in T^*_x P(\mathcal{H}), \tag{2.1.17}
\]

where the linear functional \( Q_\mathfrak{x}(v, \cdot) : w (\in T_x P(\mathcal{H})) \mapsto Q_\mathfrak{x}(v, w) \in \mathbb{R} \) depends linearly on \( v \), and for any \( F \in T^*_x P(\mathcal{H}) \) there is a unique \( v_F \in T_x P(\mathcal{H}) \) such, that \( F = Q_\mathfrak{x}(v_F, \cdot) \). Let the metric be given by

\[
Q_\mathfrak{x}(v, v) := \frac{2}{\|x\|^2} (v_x, v_x) = \frac{2}{\|x\|^2} \|v_x\|^2, \quad v_x := T_x \Psi_x(v). \tag{2.1.18}
\]

Since \( v_{\lambda x} = \lambda v_x \), the definition does not depend on the choice of \( 0 \neq x \in \mathfrak{x} \) in the mapping \( \Psi_x \). The nondegeneracy is a consequence of the Riesz theorem applied to the Hilbert space \( [x]^\perp \) and analyticity is also straightforward. From the bilinearity and symmetry we have

\[
Q_\mathfrak{x}(v, w) = \frac{2}{\|x\|^2} \Re(v_x, w_x), \quad \forall v, w \in T_x P(\mathcal{H}). \tag{2.1.19}
\]

It is possible to prove by straightforward calculations of lengths of differentiable curves in \( P(\mathcal{H}) \) (compare also [1, 262]):
2.2. SYMPLECTIC STRUCTURE

2.2.1. Let us define a complex structure \( J \) on \( P(\mathcal{H}) \) induced by that of \( \mathcal{H} \). For each \( x \in P(\mathcal{H}) \) and \( v \in T_x P(\mathcal{H}) \), we define

\[
Jv := (T_x \Psi_x)^{-1} \circ i \circ (T_x \Psi_x)(v),
\]

where \( i \) is the multiplication by the imaginary unit \( i \in \mathbb{C} \) in the complex subspace \([x]^\perp \subset \mathcal{H}\). The definition (2.2.1) of \( J \) does not depend on the choice of \( x \in x \). Clearly: \((Jv)_x = iv_x\). We define now a two-form \( \Omega \) on \( P(\mathcal{H}) \):

\[
\Omega_x(v, w) := Q_x(v, Jw), \ \forall x \in P(\mathcal{H}), v, w \in T_x P(\mathcal{H}).
\]

We shall use charts \( \Psi_x \) with \( \|x\| = 1 \) in the following. In such a chart, the form \( \Omega \) is written

\[
\Omega_x(v, w) = -2 \text{Im}(v_x, w_x).
\]

The just introduced structures lead to the standard symplectic, and also metric (known as the “Fubini-Study metric”) structures on the space of pure quantum states \( P(\mathcal{H}) \). If this both structures are connected as in (2.2.2) by a complex structure \( J \) (coming, in this case, from that in the underlying Hilbert space \( \mathcal{H} \)), we obtain a structure on the manifold \( P(\mathcal{H}) \) which is called the Kähler structure.

2.2.2 Lemma. The form \( \Omega \) is nondegenerate.

Proof. If \( \Omega_x(v, w) = 0 \) for all \( w \in T_x P(\mathcal{H}) \), then also \( \Omega_x(Jv, v) = 2 \|v_x\|^2 = 0 \), hence \( v = 0 \). \( \Box \)

2.2.3 Lemma. For any unitary transformation \( U \) of \( \mathcal{H} \) onto itself, the form \( \Omega \) is invariant with respect to the projected mapping \( \hat{U} : P(\mathcal{H}) \rightarrow P(\mathcal{H}), x \mapsto \hat{U}(x) := Ux \), i.e.

\[
(U^* \Omega)_x(v, w) := \Omega_{Ux}(U_*v, U_*w) = \Omega_x(v, w).
\]

Here \( U^* \Omega \) is the pull-back of \( \Omega \) by \( U \), and \( U_* : T_x P(\mathcal{H}) \rightarrow T_{Ux} P(\mathcal{H}) \) maps the equivalence class \( c \) containing the curve \( c : t \mapsto c(t) \) at \( x \) (i.e. \( x = c(0) \)) into the class \( Uc \) containing the curve \( Uc : t \mapsto Uc(t) \) at \( U(x) \).

Proof. According to 2.1.8, the vector \( v_x \) corresponds to the class containing the curve \( c : t \mapsto x + tv_x \), hence the vector \( (U_*v)_Ux \) corresponds to the class \( Uc \in T_{Ux} P(\mathcal{H}) \) containing the curve \( Uc : t \mapsto Ux + tUv_x \), and since \( U \) conserves orthogonality in \( \mathcal{H} \) we have

\[
(U_*v)_Ux = Uv_x.
\]

Substitution into the expression (2.2.3) from (2.2.5) gives the result. \( \Box \)
2.2.4 Proposition. The two-form $\Omega$ on $P(H)$ is closed: $d\Omega = 0$; it is a symplectic form on $P(H)$, hence strongly nondegenerate (cf. [37, A.3.14]).

Proof. The skew symmetry and bilinearity is trivial and (strong) nondegeneracy is proved in Lemma 2.2.2. The proof of closedness used in an appendix of the Arnold’s book [7, Appendix 3 B] in the finite-dimensional case is literally applicable for any complex Hilbert space and its projective space, because of the validity of Lemma 2.2.3. Hence $\Omega$ is symplectic.

2.2.5. According to a theorem by Wigner, any bijective transformation $F$ of $P(H)$ which conserves the 'transition probabilities', i.e.:

$$\text{Tr}(P_x P_y) = \text{Tr}(F(P_x) F(P_y)), \quad \forall x, y \in H, \ x \neq 0 \neq y,$$  

can be extended to a transformation $F$ of $H$ onto itself, which is either unitary or antiunitary, compare [53, 3.2.1 and 3.2.14]:

$$\text{Tr}(P_{Fx} P_{Fy}) = \text{Tr}(P_x P_y).$$  

Such transformations conserve also distances and the metric $Q$, see 2.1.2 and 2.1.9. Bijections of $P(H)$ onto itself conserving the metric $Q$ will be called the Wigner maps.

On the other hand, antiunitary transformations $F$ of $H$ do not conserve the symplectic form $\Omega : F_*\Omega = -\Omega$. Transformations $F$ of $P(H)$ conserving $\Omega$ are called symplectic transformations.

2.2.6 Lemma. Let $F$ be any symplectic transformation of $P(H)$ the restriction of which to $T_x P(H)$ for any $x \in P(H)$ (i.e. the mappings $F_* : T_x P(H) \rightarrow T_{Fx} P(H)$) are complex linear with respect to the complex structure $J$, cf. 2.2.1. Then $F$ can be extended to a unitary transformation $F \in \mathcal{L}(H)$.

Proof. Symplecticity and complex linearity of $F$ give

$$Q_x(v, w) = -\Omega_x(v, Jw) = -\Omega_{Fx}(F_*v, JF_*w) = Q_{Fx}(F_*v, F_*w),$$

i.e. $Q = F_*Q$, what implies the invariance of distances:

$$d(Fx, Gy) = d(x, y),$$

which in turn implies the invariance of $\text{Tr}(P_x P_y)$. Hence $F$ can be extended either to a unitary or to an antiunitary transformation. Since antiunitary transformations have nonsymplectic projections in $P(H)$, extension $F$ of $F$ must be unitary.

2.2.7 Proposition. Any symplectic isometry $F : P(H) \rightarrow P(H)$ is an analytic diffeomorphism of $P(H)$.

Proof. $F$ is a symplectic Wigner map, hence extendable to a unitary $F \in \mathcal{L}(H)$. With the help of the charts $\Psi_x$, analyticity follows for the projection $U$ of any unitary $U \in \mathcal{L}(H)$. The same considerations apply to the inverse map $F^{-1}$, and the assertion follows.

---

2For an alternative proof valid also for unitary orbits of density matrices see [37, Theorem 2.1.19].
2.3 Quantum mechanics as a classical Hamiltonian field theory

2.3.1. After introducing the symplectic structure $\Omega$ on the set $P(\mathcal{H})$ of all pure states of conventional QM (compare Sec.1.2), we shall try to reformulate also other concepts of QM into the form analogous to that of CM as it was outlined in Sec.1.3. It will be shown that this is possible to a large extent. There are, however, certain important differences. The main technical difference consists in infinite dimensionality of the 'phase space' $P(\mathcal{H})$ what implies e.g. nonexistence of a (Liouville) measure on $P(\mathcal{H})$, invariant with respect to all symplectic Wigner maps. The main physical difference consists, however, in the interpretation of basic quantities in QM. This difference between QM and CM does not vanish even for finite dimensional Hilbert space $\mathcal{H}$.

2.3.2. Let $A$ be a selfadjoint operator on the Hilbert space $\mathcal{H}$ with domain $D(A) \subset \mathcal{H}$. Let $PD(A) \subset P(\mathcal{H})$ be the projection of $D(A)$ into $P(\mathcal{H})$:

$$PD(A) := \{ x \in P(\mathcal{H}) : x \in D(A), x \in x \}. \quad (2.3.1)$$

Define a real-valued function $f_A$ on $PD(A)$:

$$f_A(x) := Tr(P_x A) \equiv \frac{(x, Ax)}{\|x\|^2}, \quad 0 \neq x \in x \in PD(A). \quad (2.3.2)$$

The function $f_A$ determines the operator $A$ in an unambiguous way by the polarization identity:

$$(x, Ay) = \frac{1}{4} \sum_{\lambda=\pm 1, \pm i} \lambda \|\lambda x + y\|^2 f_A(\lambda x + y). \quad (2.3.3)$$

For bounded $A \in \mathcal{L}(\mathcal{H})$, the function $f_A : P(\mathcal{H}) \to \mathbb{R}$ is real analytic. Since for arbitrary selfadjoint $A, B \in \mathcal{L}(\mathcal{H})$ there need not be any selfadjoint operator $C$ on $\mathcal{H}$ such, that $f_C := f_A \cdot f_B$ (:= pointwise multiplication of functions), the set of 'classical observables' $f_A (A^* = A \in \mathcal{L}(\mathcal{H}))$ does not form an associative algebra.

Remark: Corresponding to the spectral decomposition of $A$, we have the decomposition of $f_A$:

$$f_A(\cdot) = \int_{\mathbb{R}} \lambda E_A^f(d\lambda)(\cdot), \quad \text{where } E_A^f(B)(x) := Tr(P_x E_A(B)) \quad (2.3.4)$$

for any Borel set $B \subset \mathbb{R}$, with $E_A$ the spectral measure of $A$. Contrary to the case of classical mechanics 1.3.2, the functions $x \mapsto E_A^f(B)(x)$ are not characteristic (indicator) functions on $P(\mathcal{H})$. The decomposition into characteristic functions similar to that in 1.3.2 does not correspond to any decomposition into quantal observables.

---

3A brief review of the theory of unbounded operators is present in [37, C].
2.3.3. The function \( f_\varrho(x) := Tr(P_x \varrho) \) might remind us of a probability distribution on the "phase space" \( P(\mathcal{H}) \) representing a Gibbs ensemble in the sense of classical statistical physics, cf. e.g. [271, 272], or any textbook on statistical physics.

Although any density matrix \( \varrho \) is uniquely reconstructed from the corresponding function \( f_\varrho(x) \) on the phase space \( P(\mathcal{H}) \) with the help of (2.3.3), the function \( f_\varrho \) cannot be interpreted as a probability distribution of systems occurring in the pure states \( P_x \equiv x \) in a statistical ensemble described by \( \varrho \). The function \( f_\varrho \) is interpreted to give the probability \( f_\varrho(x) \) of positive result (i.e. of the number \( = 1 \)) by measuring of the observable \( P_x \) (with just two possible outcomes \( \in \{0, 1\} \) of any of its measurements) in the state \( \varrho \). Because of the existing nonuniqueness of decompositions of \( \varrho \) into pure states, mentioned in 1.2.3, a classical interpretation of any probability measure on \( P(\mathcal{H}) \) representing \( \varrho \) would be inadequate in general. In the following, we shall restrict our attention (mainly) to pure states.

For a quantal observable \( A \), the numbers \( f_A(x) \) are interpreted as expectation values for (real valued) results of measurements of the observable \( A \) in the state \( x \in P(\mathcal{H}) \). Also the functions \( f_A \) will be called here ‘the (quantal) observables’.

2.3.4. In the setting of this section, it is natural to define a symmetry of the system as a symplectic isometry of \( P(\mathcal{H}) \). According to the Sec.2.2, any such symmetry can be extended to a unitary transformation of \( \mathcal{H} \). Let \( t \mapsto F_t \) be a one-parameter group of symplectic isometries of \( P(\mathcal{H}) \) which is weakly continuous, i.e. the functions

\[
t \mapsto F_t x, \quad \forall x \in P(\mathcal{H})
\]

are continuous. Such a group can be extended to a weakly continuous unitary group on \( \mathcal{H} \) (compare [53, 3.2.35]), which corresponds to uniquely defined selfadjoint operator \( A \) on \( \mathcal{H} \) (by Stone’s theorem, [37, C3]). In this way, for the group \( F_t \), we obtain the expression:

\[
F_t x = \exp(-itA)x, \quad \text{i.e. } F_t x = \exp(-itA)P_x \exp(itA) \in P(\mathcal{H}).
\]

The operator \( A \) in (2.3.6) is defined by \( F_t \) up to an additive real constant multiple of identity \( I \) of \( \mathcal{L}(\mathcal{H}) \), i.e. any other \( A' \) satisfying (2.3.6) has the form \( A' = A + \lambda I \), \( \lambda \in \mathbb{R} \). Conversely, any selfadjoint operator \( A \) on \( \mathcal{H} \) determines, according to (2.3.6), a weakly continuous one-parameter group of symplectic isometries of \( P(\mathcal{H}) \). The flow \( F_t \) and its unitary extension \( F_t := \exp(-itA) \) are related by

\[
F_t(P_x) = P_{F_t x} = F_t P_x F_{-t}, \quad P_x \in P(\mathcal{H}).
\]

The functions (2.3.5) for specific \( x \)’s are differentiable if the corresponding generator \( A \) has domain \( D(A) \) containing \( x \in x : x \in D(A) \). If \( A \in \mathcal{L}(\mathcal{H}) \), then functions (2.3.5) are analytic in \( t \in \mathbb{C}, \forall x \in P(\mathcal{H}) \). It is clear from the group property of \( t \mapsto F_t \), that differentiability of (2.3.5) in any point \( x \) for \( t = 0 \) implies differentiability on the whole curve (2.3.5), i.e. for all \( t \in \mathbb{R} \).

\( ^4 \)A certain, more detailed, account of the geometry and interpretation questions of the set of density matrices is given in [37, 2.1-e].
2.3.5. We have obtained a set of differentiable curves lying densely in $P(\mathcal{H})$ for any one-parameter weakly continuous group $F_t$ of symmetries of $(P(\mathcal{H}), \Omega)$ (since $PD(A)$ is dense in $P(\mathcal{H})$ for any selfadjoint $A$). For $x \in PD(A)$ ($A$ is a generator of $F_t$), the curve (2.3.5) determines a vector $\sigma_A(x) \in T_xP(\mathcal{H})$. The set of vectors $\sigma_A(x)$ is defined for $x \in PD(A)$ only, and for unbounded $A$ it is not a differentiable vector field on $P(\mathcal{H})$ (it is differentiable only in directions of some curves lying densely in $PD(A)$, and in $P(\mathcal{H})$). We shall call it, nevertheless, ‘the vector field $\sigma_A$’. Its value in $x$ is expressed in $[x]^{-1}$ according to (2.1.16):

$$T_x\Psi_x(\sigma_A(x)) = -i(I - P_x)Ax \quad \text{for} \quad x \in D(A).$$

(2.3.8)

For $A \in \mathcal{L}(\mathcal{H})$, $\sigma_A$ is an analytic vector field on $P(\mathcal{H})$. But also for an unbounded $A$, the vector field $\sigma_A$ determines its flow $F_t =: F^A_t$ uniquely: it can be integrated along a densely in $P(\mathcal{H})$ lying set of differentiable curves (this is just the solution of Schrödinger equation with the Hamiltonian $A$), and afterwards the obtained (densely defined) flow extended to the whole $P(\mathcal{H})$ by continuity.

2.3.6. Let $x \in D(A) \cap D(B)$ for two selfadjoint operators $A$ and $B$ on $\mathcal{H}$ and $\|x\| = 1$. Then the value of the symplectic form $\Omega$ on vectors $\sigma_A(x)$ and $\sigma_B(x)$ is, according to (2.2.3) and (2.3.8),

$$\Omega_x(\sigma_A, \sigma_B) = -2\text{Im}(Ax, (I - P_x)Bx).$$

(2.3.9)

If, moreover, $Bx \in D(A)$ and $Ax \in D(B)$ (e.g. if $A$ and $B$ have a common invariant set $D \subset D(A) \cap D(B)$ and $x \in D$), then we can write

$$\Omega_x(\sigma_A, \sigma_B) = iTr(P_x[A, B])$$

(2.3.10)

Let $f$ be a real-valued function defined on a dense subset $D$ of $P(\mathcal{H})$. Let $c$ be a differentiable curve in $P(\mathcal{H})$ at $x \in D$ such, that $c(t) \in D$ for some open interval of reals $t$ containing $t = 0$, $c(0) = x$. Let $\dot{c} \in T_xP(\mathcal{H})$ be the corresponding tangent vector. Denote

$$d_xf(\dot{c}) := \frac{d}{dt} \bigg|_{t=0} f(c(t))$$

(2.3.11)

if the derivative on the right hand side exists. Assume, that (2.3.11) is well defined for a dense set of vectors $\dot{c} \in T_xP(\mathcal{H})$. The function

$$d_xf : \dot{c} \mapsto d_xf(\dot{c})$$

(2.3.12)

is linear. If it is bounded, it can be extended by continuity to the whole $T_xP(\mathcal{H})$, hence it defines an element $d_xf \in T_x^*P(\mathcal{H})$ which will be called the exterior differential of $f$ in $x$.

2.3.7 Proposition. Let $A$ be a selfadjoint operator on $\mathcal{H}$, $f_A$ is given by (2.3.2), and the corresponding vector field $\sigma_A$ is defined in 2.3.5. Then, for any $x \in PD(A)$, the exterior differential $d_xf_A \in T_x^*P(\mathcal{H})$ exists, and for all $v \in T_xP(\mathcal{H})$ we have

$$\Omega_x(\sigma_A(x), v) = -d_xf_A(v), \quad \forall x \in PD(A).$$

(2.3.13)
Proof. Let \( \{v_x\} \) be defined according to (2.1.18) for \( v \in T_x P(H) \). Define the selfadjoint \( B(v) \in \mathcal{L}(H) \):

\[
B(v)y := i(v_x, y) - i(x, y)v_x, \quad \forall y \in \mathcal{H}.
\]

(2.3.14)

Assume \( \|x\| = 1 \). Then, according to (2.1.14) and (2.1.16), the curve

\[
t \mapsto c_v(t) := \exp(itB(v))x
\]

(2.3.15)

corresponds to \( v = \dot{c}_v \). Let \( v \) be such that \( v_x \in D(A) \). Then it is seen that \( d_x f_A(v) \) defined in (2.3.11) exists and has the form

\[
d_x f_A(v) = -i \text{Tr}(P_x[B(v), A]) = -\Omega_x(\sigma_A(x), v),
\]

(2.3.16)

where, in the second equality, we used (2.3.10) and \( \sigma_B(v)(x) = -v \). Because \( (I - P_x)D(A) \subset D(A) \) is dense in \( \{x\} \), we have proved (2.3.13) for a dense linear subset \( D \subset T_x P(H), \ v \in D \). The boundednes is clear either from our construction, or from the boundednes of the left hand side of (2.3.13) for a well defined \( \sigma_A(x) \).

\[\square\]

2.3.8. We can see from the proposition 2.3.7, how to reconstruct the vector field \( \sigma_A \) from \( f_A \) with the help of the symplectic form \( \Omega \). Hence, \( \sigma_A \) is globally Hamiltonian vector field on (the dense subset of) \( P(H) \) corresponding to the Hamiltonian function \( f_A \) (compare with 1.3.5 - up to domain differences).

Let two selfadjoint \( A, B \) have a common dense domain \( D \subset D(A) \cap D(B) \). Then the function (the Poisson bracket)

\[
x \mapsto \{f_A, f_B\}(x) := \Omega_x(\sigma_A, \sigma_B), \ x \in PD,
\]

(2.3.17)

is densely defined. If, moreover, the operator \( i[A, B] \) is selfadjoint and \( D \) is its core\(^5\) then, according to (2.3.10), we have

\[
\{f_A, f_B\} = f_i[A, B].
\]

(2.3.18)

Remember that this is a quantummechanical formula corresponding to (1.3.8).

2.3.9. Assume that a weakly continuous unitary representation \( U \) of a connected Lie group \( G \) in the Hilbert space \( \mathcal{H} \) is given:

\[
U(g_1g_2) = U(g_1)U(g_2), \ g_1, g_2 \in G.
\]

(2.3.19)

Then \( U \) is projected onto a weakly continuous realization of \( G \) by a group of symplectic isometries \( U(g) (g \in G) \) of \( (P(H), \Omega) \). To any element \( \xi \) of the Lie algebra \( \mathfrak{g} \) of \( G \) corresponds the selfadjoint generator \( X_\xi \) of the one-parameter subgroup \( U(\exp(t\xi)) \):

\(^5\)A core \( D \subset \mathcal{H} \) of a closable operator \( C \) is such a subset \( D \subset D(C) \subset \mathcal{H} \), that the closure of the restriction \( C \upharpoonright D = \overline{C} \), cf. also [37, C1].
2.3. QUANTUM MECHANICS AS A CLASSICAL HAMILTONIAN FIELD THEORY

\[ X_\xi x := i \frac{d}{dt} \bigg|_{t=0} U(\exp(t\xi))x, \ x \in D(X_\xi), \] (2.3.20)

and \( U(\exp(t\xi)) = \exp(-itX_\xi) \). By a use of the adjoint representation \( Ad : G \to \mathcal{L}(g) \),

\[ Ad(g)\xi := \frac{d}{dt} \bigg|_{t=0} [g \exp(t\xi)g^{-1}] \]

we obtain:

\[ [X_\xi, X_\eta] := X_\xi X_\eta - X_\eta X_\xi = i X_{[\xi,\eta]}. \] (2.3.21)

The mapping \( \xi \mapsto X_\xi \) is linear. It is known (compare [13]), that the Gårding domain \( \mathcal{D}_G \), as well as the analytic domain \( \mathcal{A}_G \) of the representation \( U(G) \) are common dense invariant sets of all the generators \( X_\xi (\xi \in g) \) and they are also common cores of all these selfadjoint operators (cf. also 3.1.1). Let us define the vector fields \( \sigma_\xi (\xi \in g) \) on \( PD_G \subset P(\mathcal{H}) \) corresponding to the flows \( U(\exp(t\xi)) \) on \( P(\mathcal{H}) \) according to the definition of \( \sigma_A \) in 2.3.5. Let \( f_\xi(x) := \text{Tr}(P_x X_\xi) \) for \( x \in \mathcal{D}_G \). Then 2.3.8 is applicable to these quantities. All the formulas of 1.3.7 are valid on \( PD_G \). Difference w.r.t. the classical case is that neither \( P(\mathcal{H}) \) nor \( PD_G \) are homogeneous spaces even for irreducible \( U(G) \).

2.3.10. Up to now, we used charts \( (N_\chi; \Psi_\chi; [x]^{\perp}) \) for identification of \( T_xP(\mathcal{H}) \) with \([x]^{\perp} \), and for each point \( x \in P(\mathcal{H}) \) it was used its own chart. Let us rewrite now the evolution equation corresponding to the one-parameter flow \( \mathbf{F}_t^A \) on \( P(\mathcal{H}) \) generated by the Hamiltonian \( A \), i.e. the Schrödinger equation

\[ i \frac{d}{dt} x(t) = Ax(t), \ x(0) := x \in \mathcal{H}, \] (2.3.22)

projected onto \( P(\mathcal{H}) \), with the help of the chart \( (N_\gamma; \Psi_\gamma; [y]^{\perp}) \), \( x \in N_\gamma \). Let us denote by \( c : t \mapsto c(t) \) a differentiable curve in \( P(\mathcal{H}) \), and by \( \dot{c}(t) \) its tangent vector : \( \dot{c}(t) \in T_{c(t)}P(\mathcal{H}) \). The curve \( c \) will be a solution of our problem, if for some \( x \in P(\mathcal{H}) : c(t) = \mathbf{F}_t^A x \) for all \( t \in \mathbb{R} \). For \( x \in PD(A) \), we then obtain by differentiation

\[ \dot{c}(t) = \sigma_A(c(t)), \] (2.3.23)

which is an abstract form of Hamilton equations on \( P(\mathcal{H}) \) corresponding to the Hamiltonian function \( f_A \), cf. (2.3.13). The correspondence with (2.3.22) consists in that, that \( c(t) = x(t) \) if \( c(0) = x \), where \( x(t) (\in x(t)) \) is the solution of (2.3.22) with the initial value \( x \in x \). Let us fix \( y \in \mathcal{H}, \ ||y|| = 1 \), and choose the chart \( (N_\gamma; \Psi_\gamma; [y]^{\perp}) \) defined in (2.1.8). Denote

\[ \Psi(t) := \Psi_\gamma(c(t)) \text{ for a curve } c \text{ in } N_\gamma. \] (2.3.24)

The curve \( \Psi \) in \([y]^{\perp}\) will correspond to a solution \( c \) of (2.3.23) iff it satisfies the equation

\[ i \frac{d}{dt} \Psi(t) = [A - (y, A(y + \Psi(t)))](y + \Psi(t)), \ \Psi(0) \in [y]^{\perp}. \] (2.3.25)
The equation (2.3.25) describes the wanted projection of (2.3.22) onto $P(\mathcal{H})$ in the chart $\Psi_y$. It is a nonlinear (field-) equation in the Hilbert space $[y]^\perp$, in which different vectors correspond to different physical states.

If we denote by $v_y$ the representative of a vector $v \in T_x P(\mathcal{H})$ for $x \in N_y$ in the chart $\Psi_y$ ($\|y\| = 1$), then the symplectic form $\Omega$ in this chart has the expression:

$$\Omega_x(v, w) = -2 \text{Tr}(P_x P_y) \text{Im}(v_y, (I - P_x)w_y). \tag{2.3.26}$$

Remember, that $v_y, w_y \in [y]^\perp := (I - P_y)\mathcal{H}$.

Let us write $f^t := f \circ F^t_A$ for any differentiable function $f$ on $P(\mathcal{H})$. Then, for $x \in PD(A)$, we obtain the wanted form of the Schrödinger equation:

$$\frac{d}{dt} f^t(x) = \{f_A, f^t\}(x) := \Omega_x(\sigma_A, \sigma_f), \tag{2.3.27}$$

where $\sigma_f$ is a vector field defined on the whole $P(\mathcal{H})$ by

$$\Omega_x(\sigma_f(x), v) := -d_x f(v), \forall v \in T_x P(\mathcal{H}). \tag{2.3.28}$$

The equation (2.3.27) has the form of evolution equation of classical mechanics in terms of Poisson brackets.

2.3.11. Let us add a note concerning possible generalizations of the here presented dynamics. Since $P(\mathcal{H})$ is a symplectic manifold, more general Hamiltonian evolutions can be defined on it than the evolutions corresponding to linear Schrödinger equations (2.3.22). We can choose instead of the function $f_A : P(\mathcal{H}) \to \mathbb{R}$ as a (‘classical’) Hamiltonian an arbitrary ‘sufficiently differentiable’ function $h : P(\mathcal{H}) \to \mathbb{R}$. Then we obtain from the corresponding Hamiltonian dynamics on the infinite dimensional symplectic manifold $P(\mathcal{H})$ evolution of QM-vector states in $\mathcal{H}$, which cannot be described (in general) by a linear Schrödinger equation. This situation is described in many details in [37].
Chapter 3

Classical mechanical projections of QM

3.1 Orbits of Lie group actions on $P(\mathcal{H})$

3.1.1. Let $U$ be a weakly continuous unitary representation of a connected Lie group $G$ in the Hilbert space $\mathcal{H}$, and $X_\xi$ be the selfadjoint generator of the one-parameter subgroup of $U(G)$ corresponding to an arbitrary element $\xi$ of the Lie algebra $\mathfrak{g}$ of $G$, as it was defined in (2.3.20).

Let $\mathcal{D}_G \subset \mathcal{H}$ be the Gårding domain of $U(G)$ [13, 11.1.8.], i.e. a dense $U(G)$-invariant set of vectors $x \in \mathcal{H}$, for which the functions $g \mapsto U(g)x$ $(g \in G)$ are infinitely differentiable. We shall denote by $\mathcal{A}_G \subset \mathcal{H}$ the dense set of analytic vectors of $U(G)$ invariant with respect to the action of $U(G)$. For $x \in \mathcal{A}_G$, not only the functions $g \mapsto U(g)x$ are real analytic (resp. the functions $t \mapsto U(\exp(t\xi))x$ are complex analytic in a neighbourhood \(^1\) of real axis for any $\xi \in \mathfrak{g}$) in the norm of $\mathcal{H}$, but also $\mathcal{A}_G$ is invariant and analytic with respect to the Lie algebra $U(\mathfrak{g})$ of generators $X_\xi$ $(\xi \in \mathfrak{g})$; for $x \in \mathcal{A}_G$, also $X_\xi x \in \mathcal{A}_G$ $(\forall \xi \in U(\mathfrak{g}))$ and for any basis $\{X_j \in U(\mathfrak{g}) : j = 1, 2, \ldots d := \dim G\} \subset U(\mathfrak{g})$ and $x \in \mathcal{A}_G$ there is some $t \neq 0$ such that

$$\sum_{n=0}^{\infty} \frac{|t|^n}{n!} \sum_{j_1, \ldots, j_n=1}^{d} \|X_{j_1} \ldots X_{j_n}x\| < \infty, \quad (3.1.1)$$

compare [13, Chap.11.§3].

Let $U(G)$ be the projection of $U(G)$ onto $P(\mathcal{H})$, i.e. $U(G)$ is a realization of $G$ in a continuous group of symplectic isometries of $(P(\mathcal{H}), \Omega)$.\(^2\) For any $x \in P(\mathcal{H})$, define the orbit $O_x := G \cdot x$ (we shall use also the notation $g \cdot x := U(g)x$):

$$O_x = O_{g \cdot x} := \{z \in P(\mathcal{H}) : z = g \cdot x, \ g \in G\}. \quad (3.1.2)$$

Let $K^o := K^o := \{h \in G : U(h)z = z\}$ be the stability (or ‘isotropy’) group of the point $z \in O_x = O_z$. Because $P(\mathcal{H})$ is a Hausdorff space and $U$ is continuous, the group $K^o$ is closed, hence it is a Lie subgroup of $G$. The space $G/K^o$ of left cosets $gK^o \subset G$ is an

\(^1\)In the following, if not explicitly mentioned different, the word ‘neighbourhood’ in a topological space will mean ‘an open neighbourhood’.

\(^2\)Remember that if $x \equiv P_x \in P(\mathcal{H})$, then $U(g)x \equiv P_{U(g)x} \equiv U(g)P_xU(g^{-1})$. 

37
analytic manifold (with the analytic structure coming from $G$ via the natural projection, \([152, \text{Ch.II, Theorem 4.2}]\)) and it is bijectively and continuously mapped onto $O_z$ by the mapping $u : m := gK^o \mapsto U(g)z$. The orbit is not, in general, closed in $P(\mathcal{H})$ and it need not be a submanifold of $P(\mathcal{H})$, cf. also \([37, \text{Proposition 2.1.5}]\)\([47]\). The mapping $u$ induces, however, a manifold structure on $O_z$ from the analytic manifold $G/K^o$. This manifold structure is not in general consistent with the relative topology of $O_z$ in $P(\mathcal{H})$. If the map is differentiable, then we have:

3.1.2 Proposition. Let $u$ (defined as above) be continuously differentiable in a neighbourhood of a point $m \in G/K^o$, where $K^o := \{h \in G : U(h)z = z\}$. Then there is a neighbourhood $N_m$ of $m$ such that the restriction of $u$ on $N_m$ is a diffeomorphism of $N_m$ onto the submanifold $u(N_m)$ of $P(\mathcal{H})$. If $z \in PD_G$ (resp. $z \in PA_G$), then each point $m \in G/K^o$ has a neighbourhood $N_m$, which is $C^\infty$-diffeomorphic (resp. analytically diffeomorphic) to $u(N_m)$, with the submanifold structure from $P(\mathcal{H})$; in this case, the orbit $O_z$ is an immersed submanifold of $P(\mathcal{H})$.

Proof. Bijectivity of $u : G/K^o \to O_z$ and differentiability in a neighbourhood of $m$ imply, that the tangent mapping $T_mu : T_m(G/K^o) \to T_u(m)P(\mathcal{H})$ is an isomorphism onto a finite dimensional subspace of the tangent space of $P(\mathcal{H})$ at $u(m)$. Since each finite dimensional real subspace of a Banach space is complementable, the restriction of $u$ to a neighbourhood is an immersion. Hence, there is a neighbourhood $N_m$ of $m$ satisfying the first statement, compare \([74, \text{p. 549}]\). The rest is a consequence of the invariance of $PD_G$ and $PA_G$ as well as of the inverse mapping theorem, see also \([51]\).

3.1.3. We shall assume in the following that $z \in PA_G$, for the orbit $O_z$ which we shall consider. Many of the following considerations are valid, however, also for orbits passing through $z \in PD_G$. Let $\sigma_\xi$ ($\xi \in g$) be the (densely defined) vector field on $P(\mathcal{H})$ corresponding to the generator $X_\xi$ defined by \([2.3.9, 2.3.5]\). According to the definition of $O_z$, for any $x \in O_z$, the vectors $\sigma_\xi(x)$ ($\xi \in g$) are well defined, they span $T_xO_z$ and depend analytically on $x \in O_z$.

(Note: Here and in the following, we use without comments the topology on $O_z$ inherited from $G/K^o$ via the mapping $u$ introduced in 3.1.1) Let $K_x^o$ be the stability subgroup of $G$ at the point $x \in O_z$, and let its Lie algebra be $t_x^o$. Then the Lie algebra $g$ of $G$ is the direct sum

$$g = m_x^o \oplus t_x^o \quad (3.1.3)$$

of two vector spaces (the choice of $m_x^o \subset g$ is nonunique). If $\{\xi_j \in g : j = 1, 2, \ldots n := \dim O_z\}$ is a basis of $m_x^o$, then $\sigma_{\xi_j}$ span tangent spaces to $O_z$ in any point $y$ lying in some neighbourhood of $x$ in $O_z$. Then integral curves of $\sigma_{\xi_j}$ ($j = 1, 2, \ldots n$) can be used to introduce a natural coordinate system on $O_z$ in a neighbourhood of $x$ (see \([152, \text{Ch.II, Lemma 4.1}]\)). In these coordinates, the point

$$y(t) := U(\exp(t_1\xi_1 + t_2\xi_2 + \cdots + t_n\xi_n))x \in O_z \quad (3.1.4)$$

corresponds to the point $t \in \mathbb{R}^n$. We would like to interpret physically the coordinates as possible values of ‘quantities’ $\xi_j$ (where the choice of lengths of vectors $\xi_j$ corresponds to a choice of units). If we, however, take such a point of view that only the expectation values
of quantal observables \(X_\xi\) in states \(x \in P(H)\) are measurable, then, for a general orbit \(O_z\) and a group \(G\), not all values \(t \in \mathbb{R}^n\) (neither all \(t\) in any open neighbourhood of \(0 \in \mathbb{R}^n\)) are physically distinguishable. From this point of view the most natural coordinates of \(x \in P\mathcal{A}_G\) are just the values \(F_x(\xi)\) for a conveniently chosen subset of \(\xi \in \mathfrak{g}\). These values need not distinguish points of a neighbourhood of \(x \in O_z\):

\[
\frac{d}{dt} \bigg|_{t=0} F_{\exp(t\eta)\cdot x}(\xi) = F_x([\xi, \eta]), \quad \xi, \eta \in \mathfrak{g},
\]

(compare (2.3.21)), and the derivative might be zero for some nonvanishing \(\eta \in \mathfrak{m}^\circ_x\) and for all \(\xi \in \mathfrak{g}\). If it is the case, then the derivative in (3.1.6) vanish on the whole curve \(t \mapsto \exp(t\eta) \cdot x\) \((t \in \mathbb{R})\). This is easily seen with a help of the next Lemma, cf. Proposition 3.1.6:

**3.1.4 Lemma.** For all \(g \in G\) and \(\xi \in \mathfrak{g}\), we have:

\[
U(g)X_\xi U(g^{-1}) = X_{Ad(g)\xi},
\]

where the adjoint representation \(Ad\) of \(G\) is defined in 2.3.9.

*Proof.* According to the definition of \(Ad\), the curve \(t \mapsto g \exp(t\xi)g^{-1}\) at the identity \(e\) of \(G\) determines the tangent vector \(Ad(g)\xi \in T_eG\), and this one, in turn, according to the definition of the Lie algebra \(\mathfrak{g}\), determines a unique curve \(t \mapsto \exp(tAd(g)\xi)\) in \(G\) at \(e\). Hence,

\[
g \exp(t\xi)g^{-1} = \exp(tAd(g)\xi) \quad \forall t \in \mathbb{R}, g \in G, \xi \in \mathfrak{g}.
\]

From the definition (2.3.20) of the generators \(X_\xi\) of the representation \(U(G)\), we then obtain

\[
U(g) \exp(-itX_\xi)U(g^{-1}) = U(g \exp(t\xi)g^{-1}) = U(\exp(t Ad(g)\xi)),
\]

and after differentiation at \(t = 0\) we obtain (3.1.7).

**3.1.5.** Suppose now that \(F_x([\xi, \eta]) = 0\) for all \(\xi \in \mathfrak{g}\) at some \(x \in O_z\). Substitution of \(\exp(t\eta) \cdot x\) to the place of \(x\) gives according to the preceding lemma:

\[
F_{\exp(t\eta)\cdot x}([\xi, \eta]) = Tr(U(\exp(t\eta))P_x U(\exp(-t\eta))X_{[\xi, \eta]}) \quad (3.1.10)
\]
\[
= -i Tr(P_x U(\exp(-t\eta))[X_\xi, X_\eta]U(\exp(t\eta))) \quad (3.1.11)
\]
\[
= -i Tr(P_x U(\exp(-t\eta))X_\xi U(\exp(t\eta)), X_\eta) \quad (3.1.12)
\]
\[
= -i Tr(P_x [X_{Ad(\exp(-t\eta))\xi}, X_\eta]) \quad (3.1.13)
\]
\[
= F_x([Ad(\exp(-t\eta))\xi, \eta]). \quad (3.1.14)
\]

We used (2.3.7) in (3.1.10), it was used the formula (2.3.21) in (3.1.11), we considered commutativity of \(U(\exp(t\eta))\) with \(X_\eta\) in (3.1.12), and in the last step the Lemma 3.1.4 was used. According to the assumption, the expression (3.1.14) vanishes for all \(\xi \in \mathfrak{g}\), since \(Ad(g) : \mathfrak{g} \to \mathfrak{g}\). Hence we have obtained:
3.1.6 Proposition. For all $x \in PAG$, $\xi, \eta \in g$, and all $t \in \mathbb{R}$, it is

$$\frac{d}{dt} F_{\exp(t\eta)x}(\xi) = F_x([Ad(\exp(-t\eta))\xi, \eta]).$$

(3.1.15)

If, in particular, the derivative vanishes for all $\xi \in g$ at one value of $t \in \mathbb{R}$, then it vanishes for all $\xi \in g$ at all $t \in \mathbb{R}$, for the given $\eta$.

3.1.7. From the preceding considerations, we see that the numbers $F_x(\xi)$ cannot distinguish points $x$ on the integral curves of the vector fields $\sigma_\eta$ passing through $x$ iff $F_x([\xi, \eta]) = 0$ for all $\xi \in g$. Physical states lying on such curves should be identified mutually, if we could measure only expectations of observables $X_\xi$, ($\xi \in g$). Such an identification of points of orbits $O_z$ ($z \in PAG$) will be performed in the next section. After the identification, we obtain from each orbit an even-dimensional manifold endowed with canonical symplectic structure obtained from the symplectic structure $\Omega$ on $P(H)$.

3.1.8. Note that, for an irreducible representation $U(G)$, there can occur in $PAG$ mutually nonhomeomorphic orbits. But any such an orbit $O_z$, if it is considered in the Hilbert space $\mathcal{H}$ as the union of equivalence classes $x = \{z \in \mathcal{H} : z = \lambda x, \lambda \in \mathbb{C}\} \subset \mathcal{H}$ for all $x \in O_z$, contains total sets of vectors in $\mathcal{H}$. Such ‘overcomplete families of vectors’ in $\mathcal{H}$ were discussed e.g. in [18, 84, 176, 239] and they are interesting from the point of view of representation theory, as it is explained e.g. in [91], and used in [2].

3.2 Classical phase spaces from the quantal state space

3.2.1. We have constructed orbits $O_z$ of the action of $G$, $U(G)$, on $P(H)$ from pure states of conventional QM. We shall construct now symplectic homogeneous spaces of $G$ from these orbits, of which the symplectic structure is a canonical restriction of the form $\Omega$ defined on $P(H)$ in Sec. 2.2. The obtained symplectic manifolds are all symplectomorphic to the orbits of $G$ in the coadjoint representation $Ad^*(G)$ on the space $g^*$ dual to the Lie algebra $g$ endowed with the natural Kirillov-Kostant symplectic form.

3.2.2. Let $\Omega^\circ$ denotes the restriction of the form $\Omega$ onto the immersed submanifold $O_z$ ($z \in PAG$) of $P(H)$. Since the vector fields $\sigma_\xi$ ($\xi \in g$) span $T_xO_z$ at each point $x \in O_z$, the form $\Omega^\circ$ is uniquely defined by its values on vectors $\sigma_\xi(x)$ ($\xi \in g, x \in O_z$):

$$\Omega^\circ_x(\sigma_\xi, \sigma_\eta) := \Omega_x(\sigma_\xi, \sigma_\eta) = i Tr(P_x[X_\xi, X_\eta]),$$

(3.2.1)

where we used formula (2.3.10) and the restrictions of the fields $\sigma_\xi$ onto $O_z$ are equally denoted as the unrestricted fields. According to the definition (3.1.5) and with the use (2.3.21), we can write

$$\Omega^\circ_x(\sigma_\xi, \sigma_\eta) = -F_x([\xi, \eta]).$$

(3.2.2)

If we denote by

$$u_\circ : O_z = u(G/K^\circ) \to P(H)$$

such a construction of symplectic homogeneous spaces of $G$ from pure states of conventional QM should be considered as a classical limit of quantum mechanics.
3.2. CLASSICAL PHASE SPACES FROM THE QUANTAL STATE SPACE

the inclusion of the orbit into \( P(\mathcal{H}) \), then the form \( \Omega^0 \) is simply the pull-back of \( \Omega \) by \( u_z \):

\[
\Omega^0 = u_z^* \Omega. \tag{3.2.3}
\]

Since exterior derivative commutes with any pull-back, e.g. [74, p.204], we see that the two-form \( \Omega^0 \) on \( O_z \) is closed. It is clear from (3.2.2), that \( \Omega^0 \) is degenerate iff for some \( \eta \neq 0 \) and for all \( \xi \in \mathfrak{g} \) the term \( F_x(\langle \xi, \eta \rangle) = 0 \) for some \( x \) in the orbit. This is, however, the situation discussed in 3.1.7.

3.2.3. The mapping \( F_x : \mathfrak{g} \to \mathbb{R}, \xi \mapsto F_x(\xi) \) is linear because of linearity of \( \xi \mapsto X_{\xi} \), hence \( F_x \in \mathfrak{g}^* \) for any \( x \in O_z \). Define the action of \( G \) on the functionals \( F_x \) \((x \in O_z)\) by

\[
g \cdot F_x := F_{g \cdot x}, \text{ for all } g \in G. \tag{3.2.4}
\]

Then analogous computations to those in 3.1.5 lead to:

\[
F_{g \cdot x}(\xi) = F_x(Ad(g^{-1})\xi), \text{ what means: } g \cdot F_x = Ad^*(g)F_x. \tag{3.2.5}
\]

Let now \( K_x \) be, as above, the stability subgroup of \( G \) of the coadjoint action at the point \( F_x \in \mathfrak{g}^* \). Since \( Ad^* \) is continuous, \( K_x \) is closed. Let \( \mathfrak{k}_x \) be the Lie algebra of \( K_x \). Then it is clear, that:

3.2.4 Lemma. Let \( x \in P_A G \), \( y := g \cdot x \). Then \( K_y = gK_xg^{-1}, \mathfrak{k}_y = Ad(g)\mathfrak{k}_x, \text{ and } K^0_y \subset K_y \) for all \( x \) and all \( g \in G \). It is \( \xi \in \mathfrak{k}_x \) iff

\[
F_x(\langle \xi, \eta \rangle) = 0, \quad \forall \eta \in \mathfrak{g}. \tag{3.2.6}
\]

A trivial consequence of this is, according to (3.2.2), the

3.2.5 Proposition. \( \Omega^0_x(\sigma_\xi, \sigma_\eta) = 0 \) for all \( \eta \in \mathfrak{g} \) iff \( \xi \in \mathfrak{k}_x \).

3.2.6. We can decompose \( O_z \) into equivalence classes

\[
[x] := \{g \cdot x : g \in K_x\}, \quad x \in O_z \quad (z \in P_A G). \tag{3.2.7}
\]

The action of \( G \) on \( O_z \) is analytic, and \([x]\) are analytic submanifolds of \( O_z \) (if \( O_z \) is endowed with the topology of \( G/\mathfrak{k}^0_x \)) which are mutually diffeomorphic for all \( x \in O_z \). Hence \( O_z \) can be considered as a fibred manifold with a typical fibre diffeomorphic to \( K_x \cdot z = [z] \), which is in turn diffeomorphic to \( K_x/\mathfrak{k}^0_x \) \((x \in O_z)\). Let us denote the base space by \( M = M_z \):

\[
M := M_z := \{[x] : x \in O_z\}, \quad (z \in P_A G). \tag{3.2.8}
\]

which is endowed with the natural factor topology given by the continuity and openness condition on the projection

\[
p_M : O_z \to M_z, \quad x \mapsto p_M(x) := [x]. \tag{3.2.9}
\]

From the definitions (3.1.5) of \( F_x \) and of the action of \( G \) on \( F_x \) in (3.2.4), we see that \([x]\) are exactly those subsets of \( O_z \), on which expectations of all the observables \( X_\xi \) \((\xi \in \mathfrak{g})\) remain constant.
3.2.7 Lemma. \( \Omega^\circ_{h,x}(\sigma_\xi, \sigma_\eta) = \Omega^\circ_x(\sigma_\xi, \sigma_\eta) \) for all \( h \in K_x \) and all \( \eta, \xi \in \mathfrak{g} \).

Proof. Immediate from (3.2.2) and the definition of \( K_x \).

3.2.8. Let \( p_{M*} := TP_M : TO_x \rightarrow TM_z \) be the tangent mapping corresponding to the natural projection (3.2.9). For a general vector field \( \sigma \) on \( O_x \), the vectors \( TP_M \sigma(x) \) are mutually different for various choices of \( x \in [z] \). Let, however, \( t \mapsto g(t) \) be any differentiable curve in \( G \). Then curves \( t \mapsto g(t) \cdot x \) and \( c_h : t \mapsto g(t)h \cdot x \) for any \( h \in K_x \) are projected by \( p_M \) onto the same curve \( t \mapsto [g(t) \cdot x] \) in \( M_z \). This is true due to the validity of

\[
[g \cdot x] = K_{g \cdot x}g \cdot x = gK_xg^{-1}g \cdot x = gK_x \cdot x, \tag{3.2.10}
\]

for all \( g \in G \),

\[
[gh \cdot x] = ghK_x \cdot x = gK_x \cdot x = [g \cdot x], \quad \forall h \in K_x, \ g \in G. \tag{3.2.11}
\]

Hence tangent vectors \( \dot{c}_h \in T_{h \cdot x}O_x \) corresponding to the curves \( c_h \) with \( g(t = 0) := e \) have identical projections \( TP_M(c_h) = TP_M(\dot{c}_e) \in T[x]M_z \) for all \( h \in K_x \). If we set \( g(t) := \exp(t\xi), \) i.e. \( \dot{c}_h = \sigma_\xi(h \cdot x) \), then we have obtained:

3.2.9 Lemma. All the vector fields \( \sigma_\xi (\xi \in \mathfrak{g}) \) on \( O_x \) are projected onto unambiguously defined (analytic, if \( z \in P\mathcal{A}_G \)) vector fields \( \sigma_\xi^M \) on \( M_z \):

\[
\sigma_\xi^M([x]) := TP_M\sigma_\xi(h \cdot x) \tag{3.2.12}
\]

for all \( h \in K_x \).

3.2.10 Proposition. There is a unique symplectic form \( \Omega^M \) on \( M_z \) satisfying

\[
\Omega^M_{\mathfrak{g}}(\sigma^M_\xi, \sigma^M_\eta) = \Omega^\circ_x(\sigma_\xi, \sigma_\eta) = (p^*_M \Omega^M)_x(\sigma_\xi, \sigma_\eta) \tag{3.2.13}
\]

for all \( \xi, \eta \in \mathfrak{g} \) and all \( x \in O_x, p^*_M \) in (3.2.12) is the pull-back corresponding to the projector \( p_M \) (compare [1], resp. also [37, A.3.11] for the definition).

Proof. The first equality can be considered as a definition of a two-form \( \Omega^M \), which is correct due to two preceding lemmas and the fact, that vectors \( \sigma^M_\xi(p_Mx) (\xi \in \mathfrak{g}) \) contain a basis of \( T_{[x]}M_z : \eta^M(p_Mx) = 0 \) implies \( \eta \in \mathfrak{f}_x \) and \( M_z \) is diffeomorphic to \( G/K_x \). This ensures also the uniqueness of \( \Omega^M \). The second equality is a consequence of the definition (3.2.12) of \( \sigma^M_\xi \) and it shows, how \( \Omega^\circ \) can be reconstructed from \( \Omega^M \).

The bilinearity of \( \Omega^M \) follows from linearity of the mapping \( T_xp_M \) and the bilinearity of \( \Omega^\circ \), antisymmetry is trivial and closedness holds due to commutativity of the exterior derivative with the pull-bacs: \( dp^*_M = p^*_M d \), and due to closedness of \( \Omega^\circ \). Nondegeneracy follows from (3.2.1) and 3.2.4, which completes the proof.

3.2.11. As it was pointed out, the manifold \( M := M_z \) \( (z \in P\mathcal{A}_G) \) is diffeomorphic to \( G/K_z \), where \( K_z \) is the stability group of the point \( F_z \in \mathfrak{g}^* \) with respect to the coadjoint representation of \( G \). On the other hand, the form \( \Omega^M \) on \( M \) has the expression
3.3. CLASSICAL MECHANICAL PROJECTIONS OF QUANTAL DYNAMICS

\[ \Omega^M_{[z]}(\sigma^M_\xi, \sigma^M_\eta) = -F_z([\xi, \eta]), \]  
(3.2.14)

which follows from (3.2.2). This is, up to the sign, the canonical symplectic form on the orbit of \( Ad^* (G) \) passing through \( F_z \) and diffeomorphic to \( G/K_z \). Hence the symplectic manifold \((M; \Omega^M)\) is symplectomorphic to a Kirillov-Kostant symplectic orbit, compare [174]. This manifold is here interpreted as a classical phase space obtained by the above described canonical procedure from a given quantal system, in which interpretation of observables is (at least partly) determined by a Lie group action \( U(G) \). This action is projected on the coadjoint action \( Ad^* (G) \) on \( M \), see (3.2.5). Almost obvious is the following

3.2.12 Proposition. The vector fields \( \sigma^M_\xi (\xi \in g) \) are globally Hamiltonian vector fields on the symplectic manifold \((M; \Omega^M)\) corresponding to Hamiltonian functions

\[ f_\xi : [x] \mapsto f_\xi([x]) := F_x(\xi). \]  
(3.2.15)

They generate Hamiltonian flows \( F^\xi_t \) on \( M \):

\[ F^\xi_t : [x] = p_M x \mapsto F^\xi_t(p_M x) := p_M (U(exp(t\xi))x). \]  
(3.2.16)

Proof. From the definition of \( \sigma^M_\xi \) in 3.2.8 and 3.2.9 the relation (3.2.16) follows. Differentiation of \( f_\xi \) according to (3.1.15) and (3.2.2) gives

\[ df_\xi = -i(\sigma^M_\xi)\Omega^M, \]  
(3.2.17)

compare (1.3.4). This proves the first statement.

With the usual definition of Poisson brackets on \((M; \Omega^M)\), we obtain the obvious (compare also (1.3.11) + (1.3.12))

3.2.13 Lemma. \( \{f_\xi, f_\eta\} = -f_{[\xi, \eta]} \) for all \( \xi, \eta \in g \).

3.2.14. This shows, that the action of \( Ad^* (G) \) is strictly Hamiltonian. Since for the generators of \( U(G) \) in \( \mathcal{H} \) we have \( X_{[\xi, \eta]} = -i[X_\xi, X_\eta] \), (2.3.21), the Lemma 3.2.13 establishes the usual correspondence between classical and quantal observables associated with generators of the group action.

3.3 Classical mechanical projections of quantal dynamics

3.3.1. Let the time evolution of a given system in QM be described by a one parameter subgroup of \( U(G) \) corresponding to an element \( \chi \in g \). Then, for a given \( z \in P(\mathcal{H}) \), the flow \( U(exp(t\chi)) \) leaves the orbit \( O_z \) invariant. If \( z \in P.A_G \), then this flow is projected onto the Hamiltonian flow on \( M_z \) generated by the Hamiltonian function \( f_\chi \) with the corresponding Hamiltonian vector
field $\sigma^M_X$, as it was described above. Models one frequently encounters are, however, in which the time evolution is given by a one parameter group of unitaries $U_A(\mathbb{R})$:

$$U_A : t \mapsto U_A(t) := \exp(-itA), \quad A = A^*,$$

(3.3.1)

where the generator $A$ has not the form $X_\chi$ for any $\chi \in \mathfrak{g}$. The orbits $O_z$ are then in general not invariant with respect to the action of $U_A(\mathbb{R})$. We shall be interested here in the question whether and how such an action $U_A(\mathbb{R})$ can be projected onto a Hamiltonian flow on $M_z$.

### 3.3.2

Let $A$ be any selfadjoint operator on $\mathcal{H}$ and $E_A$ the corresponding projector-valued measure on $\mathbb{R}$. Assume that $z \in P\mathcal{A}_G$ (defined in 3.1.1) and that $O_z := U(G)z$ is contained in the form domain of $A$, i.e. the integral in

$$f_A(x) := Tr(P_xA) := \int_{\mathbb{R}} \lambda Tr(P_xE_A(d\lambda))$$

(3.3.2)

converges absolutely for all $x \in O_z$. In an analogy with the constructions of the preceding sections, the function $f_A$ will be considered as a candidate for a classical observable corresponding to the quantal observable $A$. We shall require that

$$f_A \in C^\infty(O_z).$$

(3.3.3)

This requirement is fulfilled in the following situation:

### 3.3.3 Lemma. Let $\mathcal{E}(\mathfrak{g})$ be the linear space of all polynomials in selfadjoint generators $X_\xi$ ($\xi \in \mathfrak{g}$) of $U(G)$ with complex coefficients. Assume that for a fixed $z \in P\mathcal{A}_G$ and for any $x \in O_z$ and any $E \in \mathcal{E}(\mathfrak{g})$ there is an open neighbourhood $N(x, E)$ of the identity $e \in G$ such, that the function

$$g \mapsto \|AEU(g)x\| \quad (x \in x)$$

(3.3.4)

is uniformly bounded on $N(x, E)$. Here $A$ is a given symmetric operator on $\mathcal{H}$ containing $\mathcal{E}(\mathfrak{g})U(G)z := \{EU(g)z : E \in \mathcal{E}(\mathfrak{g}), \quad g \in G\}$ in its domain $D(A)$, $z \in z$. Set $f_A(x) := (x, Ax)$ for $\|x\| = 1$, $x \in x \in O_z$. Then $f_A$ is infinitely differentiable on $O_z$.

**Proof.** It suffices to prove infinite differentiability of the function $g \mapsto f_A(g \cdot x)$ defined on $G$. For any $E_1, E_2 \in \mathcal{E}(\mathfrak{g})$ the functions $g \mapsto E_jU(g)x$ ($j = 1, 2$) are norm-analytic according to (3.1.1), see also [13]. Consequently, the function

$$(g_1; g_2) \mapsto (E_1U(g_1)x, AE_2U(g_2)x) \text{ from } G \times G \text{ to } \mathbb{C}$$

(3.3.5)

is infinitely differentiable in each variable $g_1, g_2$ separately and any partial derivative (in the direction of some one parameter subgroup of $G$) has the form (3.3.5) (with some other $E_j$’s). To prove differentiability of

$$g \mapsto (E_1U(g)x, AE_2U(g)x),$$

(3.3.6)
it suffices to prove simultaneous continuity of all functions of the form (3.3.5) in both variables $g_1, g_2$. It follows, however, from the assumption of uniform boundedness on $N(x, E_2)$, analyticity of $U(g)x$ with respect to $U(G)$ and continuity of $U(g)$:

$$||(E_1U(g_1)x, AE_2U(g_2)x) - (E_1x, AE_2x)|| \leq \|E_1(U(g_1) - I)x\| \cdot \|AE_2U(g_2)x\| + \|E_2(U(g_2) - I)x\| \cdot \|AE_1x\|. \quad (3.3.7)$$

This concludes the proof.

3.3.4. If the assumptions of the preceding lemma are valid for $A$, the explicit expressions for the partial derivatives $\partial_\xi f_A$ along the curves $t \mapsto e^{\imath t\xi} \cdot x$ have the form ($\|x\| = 1$, $\xi, \eta \in \mathfrak{g}$):

$$\partial_\xi f_A(x) = 2 \imath \text{Im}(x, AX_\xi x), \quad (3.3.8)$$
$$\partial_\eta \partial_\xi f_A(x) = 2 \text{Re}[(X_\xi x, AX_\eta x) - (x, AX_\xi X_\eta x)], \quad (3.3.9)$$

and similarly for higher derivatives. For these expressions, we shall use also forms which are literally valid only if the set $\mathcal{E}(\mathfrak{g})U(G)x$ is mapped by $A$ into $D_G$:

$$\partial_\xi f_A(x) =: i \text{Tr}(P_x[X_\xi, A]), \quad (3.3.10)$$
$$\partial_\eta \partial_\xi f_A(x) =: i^2 \text{Tr}(P_x[X_\eta, [X_\xi, A]]), \quad (3.3.11)$$

e tc. Also in more general cases, we shall write symbolically

$$i \text{Tr}(P_x[X_\xi, A]) := f_{i[X_\xi, A]}(x) := \partial_\xi f_A(x). \quad (3.3.12)$$

The Definition 3.3.6 (ii) deals with such symbols.

3.3.5 Examples. Assumptions of the Lemma 3.3.3 are satisfied, e.g. for

(i) all bounded operators $A = A^* \in \mathcal{L}(\mathcal{H})$,

(ii) all symmetric operators $A \in \mathcal{E}(\mathfrak{g})$.

3.3.6 Definitions. (i) Let $A$ be a symmetric operator on $\mathcal{H}$ with $O_z \subset D(A)$ for some $z \in P\mathcal{A}_G$ and let $f_A : x \mapsto f_A(x) := \text{Tr}(P_x A)$ be infinitely differentiable on $O_z$. Let $K_x$ be the stability group of $F_x \in \mathfrak{g}^*$, $F_x(\xi) := \text{Tr}(P_x X_\xi)$, with respect to the coadjoint representation of $G$ and $[x] := K_x \cdot x \ (x \in O_z)$. If

$$f_A([x]) := f_A(x) = f_A(h \cdot x), \quad \forall h \in K_x, \forall x \in O_z, \quad (3.3.13)$$

the operator $A$ will be called a $U(G)$-classical operator on $O_z$ or simply a z-classical operator.

(ii) Let $A := A_1A_2 \ldots A_n$ be formal product of some selfadjoint operators $A_j^* = A_j$, $j = 1, 2, \ldots n$. Let $A_0 := I$. Suppose, that for some $j \in \{0, 1, 2, \ldots n\}$ the products $A_{j+1} \ldots A_n$ and
A_j A_{j-1} \ldots A_1 A_0 are well defined operators with \( U(G)z \) \((0 \neq z \in \mathbb{z})\) lying in the intersection of their domains. Denote then (with \( x \in \mathbb{x}, \|x\| = 1, x \in O_z \))

\[
f_A(x) := f_{A_1 A_2 \ldots A_n}(x) := (A_j A_{j-1} \ldots A_1 x, A_{j+1} A_{j+2} \ldots A_n x).
\] (3.3.14)

For any other \( j \in \{1, \ldots n\} \) satisfying these conditions the values in (3.3.14) will be the same. If \( f_A \in C^\infty(O_z) \) and if (3.3.13) is valid (with \( A \mapsto A \)) for \( f_A \), then \( A \) will be called a \underline{generalized \( z \)-classical operator}. The same name will be given to any formal complex finite linear combination \( B \) of generalized \( z \)-classical operators \( A^\tau := A_1^\tau A_2^\tau \ldots A_n^\tau \):

\[
B := \sum_\tau \lambda_\tau A^\tau,
\] (3.3.15)

and we shall set

\[
f_B([x]) := f_B(x) := \sum_\tau \lambda_\tau f_A^\tau(x).
\] (3.3.16)

The adjective ‘generalized’ will be sometimes omitted.

3.3.7 Examples.  
(i) All the generators \( X_\xi \) \((\xi \in \mathfrak{g})\) are \( z \)-classical for all \( z \in P A_G \).

(ii) If, for some \( z \in P(\mathcal{H}) : K_z = K_z^\circ \), (cf. 3.1.1) and \( f_A \in C^\infty(O_z) \), then \( A \) is \( z \)-classical.

(iii) If \( A \) is \( z \)-classical and \( X_{\xi}, \ldots X_\chi \in \mathcal{U}(\mathfrak{g}) \), then all the symbols \([X_{\xi}, [X_\eta, \ldots [X_\chi, A] \ldots]]\) represent generalized \( z \)-classical operators. We can see this from 3.3.4 and (3.2.11):

\[
f_A(g \cdot z) = f_A([g \cdot z]) = f_A([gh \cdot z])
\]

and differentiations and induction give the result.

(iv) Let \( f_A \in C^\infty(O_z) \) and all the \( K_x \) be symmetry groups of the observable \( A : U(h^{-1})A U(h) = A \) for all \( h \in K_x \) and all \( x \in O_z \) (e.g. if \( K_z \) is a normal subgroup of \( G \) and \( K_z \) is a symmetry group of \( A \)). Then \( A \) is \( z \)-classical.

3.3.8. If \( A \) is \( z \)-classical, then the function \( f_A \) can be considered as a function on \( M_z \) according to (3.3.13) and then \( f_A \in C^\infty(M) \). Denote by \( \sigma_A^M \) the \underline{Hamiltonian vector field on \( M \)} corresponding to the Hamiltonian function \( f_A : m \mapsto f_A(m), m \in M \). Choose a system \( \sigma_j \) \((j = 1, \ldots \dim M)\) of vector fields on \( M \) forming a basis of \( T_m M \) for all \( m \) in a neighbourhood of \( m_0 \in M \). Since the symplectic form \( \Omega^M \) is nondegenerate, the inverse matrix to \( \Omega_M^M(\sigma_j, \sigma_k) \) with elements \( \Omega_M^{ij}(m) \) \((j, k = 1, 2, \ldots \dim M)\) exists:

\[
\sum_i \Omega_M^{ij}(m) \Omega_M^{ji}(\sigma_i, \sigma_k) = \sum_i \Omega_M^{ij}(\sigma_k, \sigma_i) \Omega_M^{ji}(m) = \delta_{jk}.
\] (3.3.17)

From the connection between Hamiltonian vector fields and corresponding Hamiltonian functions, we obtain:
3.3. CLASSICAL MECHANICAL PROJECTIONS OF QUANTAL DYNAMICS

\[ \sigma^M_A(m) = \sum_{j,k} \Omega^{jk}_M(m) d_m f_A(\sigma_k) \sigma_j(m). \]  

(3.3.18)

For Poisson brackets of functions \( f_A \) and \( f_B \) on \( M \) corresponding to \( z \)-classical operators \( A \) and \( B \), we obtain with a help of (3.3.17):

\[ \{ f_A, f_B \}(m) := \Omega^M_m(\sigma^M_A, \sigma^M_B) = - \sum_{j,k} d_m f_A(\sigma_j) \Omega^{jk}_M(m) d_m f_B(\sigma_k). \]  

(3.3.19)

If \( \sigma_j \) are Hamiltonian vector fields corresponding to generators \( X_j \in U(g) \), then we obtain according to (3.3.12)

\[ d_m f_A(\sigma_j) = f_i[X_j,A](m) \]  

(3.3.20)

and the Poisson bracket (3.3.19) has the form

\[ \{ f_A, f_B \}(m) = - \sum_{j,k} f_i[X_j,A](m) \Omega^{jk}_M(m) f_i[X_k,B](m). \]  

(3.3.21)

If the operator \( B \) is one of the generators of \( U(G) \), \( B := X \in U(g) \), then the Poisson bracket (3.3.21) has the expression:

\[ \{ f_A, f_X \}(m) = i Tr(P_x[A,X]) = f_i[A,X](m), \]  

(3.3.22)

where \( x \in x \in [x] := m \in M \). The results (3.3.21) and (3.3.22) have to be compared with 3.2.14.

If the orbit \( O_z \) coincides with the manifold \( M := M_z \), then the vector field \( \sigma^M_A \) in (3.3.18) is the skew-orthogonal projection of \( \sigma_A \) (from (2.3.8)) onto \( M \), the skew-orthogonality being defined by the form \( \Omega \) on \( P(H) \), see Sec. 2.2.

3.3.9. The unitary group \( U_A : t \mapsto U_A(t) := \exp(-itA) \) does not leave the orbit \( O_z \) invariant for a general selfadjoint \( z \)-classical operator \( A \). Then we would like to compare the classical Hamiltonian evolution on \( M_z \) generated by \( f_A \) (with the flow \( F^A_t \)) and the quantal evolution on \( P(H) \) described by the flow \( U_A(t) \). From the point of view of this work, the 'quantities of interest' are generators of the representation \( U(G) \). The evolutions of the corresponding functions \( f_X \) \((X = X^* \in U(g))\) are described by

\[ \frac{d}{dt} f^t_X = \{ f_A, f^t_X \} = f^t_i[A,X] \]  

(3.3.23)

in both cases of the classical flow \( F^A_t \) as well as of the quantal evolution \( U_A(t) \), compare 3.2.12, (2.3.27) and (3.3.22). The difference is between the two cases in the meaning of \( f^t \):

(i) In the case of the flow \( F^A_t \) on \( M \) for any \( f \in C^\infty(M) \), we define

\[ f^t(m) := f(F^A_t m), \quad m \in M, \]  

(3.3.24)

and the flow \( F^A_t \) has to be determined from (3.3.23) \((\forall X^* = X \in U(g))\).
(ii) In the quantal case, we have given the flow \( U_A \) on \( P(\mathcal{H}) \) and for functions \( f \) on (the dense \( U_A \)-invariant subset of) \( P(\mathcal{H}) \) we set
\[
f^t(x) := f(U_A(t)x).
\]
(3.3.25)
The functions \( f_B \) for any \( z \)-classical \( B \) are defined in the both cases by the formula
\[
f_B(x) := \text{Tr}(P_xB).
\]
(3.3.26)
The ‘classical \( f_B \)’ is the restriction of the ‘quantal \( f_B \)’ to the manifold \( M := M_z \). The classical flow is the specific kind of restriction of the flow \( U_A \) onto \( M \) (compare (3.3.18) and the note in the last sentence of 3.3.8).

Although the rules for computation of the functions
\[
t \mapsto f_X(F^A_{\tau}[x]), \ [x] \in M_z, \ X = X^* \in U(\mathfrak{g}),
\]
and
\[
t \mapsto f_X(U_A(t)x), \ x \in [x] \in M_z, \ X = X^* \in U(\mathfrak{g}),
\]
(3.3.27)
(3.3.28)
seem to be very similar, the mutually corresponding functions from (3.3.27) and (3.3.28) might be radically different for an abstractly defined selfadjoint (\( z \)-classical) operator \( A \). We shall give in the next chapter an example, in which both the functions from (3.3.27) and (3.3.28) (given by the same \( X \in U(\mathfrak{g}) \) and with the same initial condition \( x \in O_z \)) are periodic with different periods (and, moreover, with mutually different dependence of these periods on the initial condition \( x \)); the corresponding orbits in \( g^* \):
\[
\{F^d_{[x]}(t) : t \in \mathbb{R}\} \subset g^*, \text{ with } F^d_{[x]}(t) : \xi \mapsto f_{X^*}(F^A_{\tau}[x]), \ \xi \in \mathfrak{g},
\]
(3.3.29)
and the orbit
\[
\{F^d_X(t) : t \in \mathbb{R}\} \subset g^*, \text{ where } F^d_X(t) : \mathfrak{g} \to \mathbb{R}, \ \xi \mapsto F^d_X(t)(\xi) := f_{X^*}(U_A(t)x),
\]
(3.3.30)
are mutually different closed curves in \( g^* \), see 4.1.10.

3.3.10. We expect, contrary to the above mentioned example, that in certain situations the parametrized curves in \( g^* \) defined in (3.3.27) and (3.3.28) will be in some sense close one to another, at least for not too large times \( t \in \mathbb{R} \). We mean namely such situations, in which \( A \) is the Hamiltonian operator of a ‘realistic’ quantal model and the initial condition \( x \) leads to subsequent evolution \( U_A(t)x \), which is sufficiently well approximated by laws of CM. For some estimates in these directions, they might be useful Taylor expansions of the functions in (3.3.27) and (3.3.28) in the initial point \( t = 0 \). Set, as usual,
\[
\{f_A, f_X\}^{(n)} := \{f_A, \{f_A, f_X\}^{(n-1)}\}, \ \{f_A, f_X\}^{(0)} := f_X, \ \text{for } n \in \mathbb{Z}_+.
\]
(3.3.31)
and also the corresponding notation for multiple commutators for operators. Then we have expressions for derivatives

\[ \left. \frac{d^n}{dt^n} f_X(F_t^A[x]) \right|_{t=0} = \{ f_A, f_X \}_n(x), \quad (3.3.32) \]

and

\[ \left. \frac{d^n}{dt^n} f_X(U_A(t)x) \right|_{t=0} = i^n \text{Tr}(P_x[A, X]_n) =: f_i^n[A, X]_n(x). \quad (3.3.33) \]

The right hand side of (3.3.32) can also be expressed as a polynomial in expectation values of quantal observables in the initial state \( x \) by multiple application of (3.3.21). To make these formulae clearly applicable it is necessary to have some assumptions on the domain of \( A \), e.g. let \( A \) be \( z \)-classical with \( O_z \) in its invariant analytic domain, \( x \in O_z \) and \( A^n x \in \mathcal{A}_G \) (:= the analytic domain of \( U(g) \)) for all \( n \in \mathbb{Z}_+ \). If these assumptions are fulfilled, then the identity of functions (3.3.27) and (3.3.28) (for given \( X \in U(g) \) and \( x \in O_z \)) is equivalent to the equality of the right hand sides in (3.3.32) and (3.3.33) for all \( n \in \mathbb{Z}_+ \). This equality holds for any such \( A \) for \( n = 0, 1 \). The equality in higher orders is essentially dependent on the choice of \( A \).

Content of this subsection is closely related to the investigation of \( \hbar \to 0 \) limit of quantal correlation functions in the work by Hepp [154], cf. also 4.1.8 - 4.1.10.

3.3.11. Extended phase spaces: If the one-parameter group of time evolution is included into \( G \) as a subgroup, the reduction of the orbits \( O_z \) to the symplectic manifolds \( M_z \) can be sometimes replaced by a natural procedure of a reduction of \( O_z \) to odd dimensional manifolds of the dimension \( 2n + 1 \), if the dimension of the corresponding classical phase space is equal to \( 2n \). In this case, the restriction of the form \( \Omega^o \) to such a manifold is degenerate, of the rank \( 2n \). Such odd dimensional manifolds with a given closed two-form of the maximal rank are called contact manifolds. Usage of contact manifolds in CM is convenient for a natural possibility of passing to moving reference frames. Another situation, in which they are useful is that of time dependent Hamiltonians, cf. [1, Ch. 5], and also [111, Sec. 18.5].

Sometimes it is useful to describe mechanical systems in CM by symplectic manifolds which are of the dimension higher by 2 than the usual ones. Any symplectic manifold can be extended to a contact manifold and any contact manifold can be extended to a symplectic manifold, each time increasing the dimension by one.

We shall not try to give here the theory of these situations. For generalities on such structures cf. e.g. [1, 7]. Some cases will be mentioned in the following chapter.
Chapter 4

Examples of classical mechanical projections

4.1 The Heisenberg group (CCR)

4.1.1. A physical system consisting of the finite number \( N \) of nonrelativistic (apriori mutually distinguishable) point particles is described in the conventional QM by an infinite dimensional unitary irreducible representation of the \( 2n + 1 \) -dimensional Heisenberg group \( G \) (\( n := N\nu \), \( \nu \) is the dimension of the one-particle configuration space); cf. also [37, Sec. 3.3-b]. The Heisenberg group \( G \) is a central extension by \( \mathbb{R} \) of the commutative group \( \mathbb{R}^{2n} \) (which can be identified with the classical flat phase space \( \mathbb{R}^{2n} = T^*\mathbb{R}^n \)), compare [321] and [346]. The (scalar multiples of the) selfadjoint generators \( X_j, j = 1, 2, \ldots 2n \), of the representation correspond to basic ‘kinematical’ observables of the system. The choice of \( X_j's \) is conveniently made in such a way, that on corresponding domains (e.g. on \( D_G \)) the commutation relations (CCR) are fulfilled:

\[
[X_j, X_k] = i S_{jk} X_0 \quad \text{for} \quad j, k = 1, 2, \ldots 2n; \quad (4.1.1a)
\]

\[
[X_j, X_0] = 0, \quad j = 1, 2, \ldots 2n. \quad (4.1.1b)
\]

Here the elements \( S_{jk} \) of the \( 2n \times 2n \) real matrix \( S \) are defined:

\[
S_{j+n} = -S_{j+n}, \quad S_{j+n} = 1, \quad j = 1, 2, \ldots n, \quad S_{jk} = 0 \quad \text{otherwise.} \quad (4.1.2)
\]

Hence \( S^{-1} = S^T = -S \) where \( S^T \) is the transposed matrix to \( S \). From (4.1.1b) we see, that

\[
X_0 = \hbar I, \quad (I \text{ is the identity of } \mathcal{L}(\mathcal{H})). \quad (4.1.3)
\]

The parameter \( \hbar \in \mathbb{R}, \ h \neq 0 \), (\( \hbar := \text{the ‘Planck constant'} \), if its value is chosen properly) classifies all infinite-dimensional unitary irreducible representations of \( G \); representations corresponding to various values of \( \hbar \) are mutually inequivalent, [346]. Setting

\[
Q_j := X_j, \quad P_j := X_{j+n} \quad \text{for} \quad j = 1, 2, \ldots n \quad (4.1.4)
\]
we obtain from (4.1.1a) the usual form of the canonical commutation relations (CCR). There is only one physically admissible choice of the constant \( \hbar \): it is the Planck constant divided by \( 2\pi \) (its numerical value depends on a choice of physical units for determination of which it is necessary to consider also dynamics). Operators \( Q_j \) (resp. \( P_j \)) are interpreted to correspond to observables called 'coordinates of the configuration' (resp. 'coordinates of the linear momentum'), in a cartesian basis. Note, that this representation of \( G \) can be considered as a projective representation of \( \mathbb{R}^{2n} \), as it was described in 1.2.7.

4.1.2. The Schrödinger form of the above mentioned representation of \( G \) consists of the realization of the Hilbert space \( \mathcal{H} \) of the representation as \( L^2(\mathbb{R}^n, d^nq) \) (\( d^nq \) is the Lebesgue measure) and the action of \( X_j \)'s can be defined on such \( \varphi \in L^2(\mathbb{R}^n, d^nq) \), which belong to Schwartz test functions:

\[
(X_j \varphi)(q_1, q_2, \ldots q_n) := q_j \varphi(q_1, q_2, \ldots q_n) \quad (4.1.5a)
\]

and

\[
(X_{j+n} \varphi)(q_1, q_2, \ldots q_n) := -i\hbar \frac{\partial}{\partial q_j} \varphi(q_1, q_2, \ldots q_n) \quad (4.1.5b)
\]

for \( j = 1, 2, \ldots n \). An equivalent realization of CCR is obtained by an arbitrary unitary transformation \( U \) of \( \mathcal{H} \) onto itself, e.g. by the scaling \( U = U_\lambda (\lambda \in \mathbb{R}_+ \setminus \{0\}) \):

\[
(U_\lambda \varphi)(q) := \lambda^{n/2} \varphi(\lambda q). \quad (4.1.6)
\]

It is \( U_\lambda^{-1} = U_{1/\lambda} \) and we have:

\[
X'_j := U_\lambda X_j U_\lambda^{-1} = \lambda X_j, \quad X'_{j+n} := U_\lambda X_{j+n} U_\lambda^{-1} = \frac{1}{\lambda} X_{j+n}, \quad j = 1, 2, \ldots n. \quad (4.1.7)
\]

These transformations are useful for taking limits \( \hbar \to 0 \), compare [154, 34] and also our 4.1.8.

4.1.3. Let \( X \cdot S \cdot x := X_j S_{jk} x_k \) with summation over \( j, k = 1, 2, \ldots 2n \), where \( x_k \in \mathbb{R} \) for all \( k \). Let \( W_x \) (\( x \in \mathbb{R}^{2n} \)) be unitary operators of the above mentioned projective representation:

\[
W_x := \exp(\frac{i}{\hbar} X \cdot S \cdot x). \quad (4.1.8)
\]

From (4.1.1a) we obtain

\[
W_x^{-1} X_j W_x = X_j + x_j I, \quad (4.1.9)
\]

\[
W_{x+x'} = \exp(\frac{i}{\hbar} x \cdot S \cdot x') W_x W_{x'}. \quad (4.1.10)
\]
Let us mention here, that the multiplier in (4.1.10) is determined by the standard symplectic form $\Omega^c$ on the classical flat phase space $\mathbb{R}^{2n}$; setting $q_j := x_j$, $p_j := x_{j+n}$ for $j = 1, 2, \ldots n$, it is

$$\Omega^c := \sum_{j=1}^{n} dp_j \wedge dq_j,$$  \hspace{1cm} (4.1.11)

$$x' \cdot S \cdot x = \Omega^c(x, x').$$  \hspace{1cm} (4.1.12)

4.1.4. Let $\varphi \in \mathcal{A}_G :=$ the analytic domain of $U(G)$, $\|\varphi\| = 1$, $\varphi_x := W_x \varphi$ ($x \in \mathbb{R}^{2n}$). Let $P^\varphi_x \in P(\mathcal{H})$ be the corresponding projectors, $Tr(P^\varphi_x A) := (\varphi, A\varphi_x)$ ($A \in \mathcal{L}(\mathcal{H})$) and $P^\varphi_0 = P_\varphi$. From (4.1.9) one has

$$Tr(P^\varphi_x X_j) = Tr(P_\varphi X_j) + x_j.$$  \hspace{1cm} (4.1.13)

Hence the mapping $P^\varphi : x \mapsto P^\varphi_x$ is a bijection of $\mathbb{R}^{2n}$ onto the orbit $O_\varphi := \{P^\varphi_x : x \in \mathbb{R}^{2n}\}$ and it is continuous if $O_\varphi$ is taken in the relative topology from $P(\mathcal{H})$. Due to absolute continuity of spectra of all $X_j$ ($j = 1, 2, \ldots 2n$) with respect to the Lebesgue measure on $\mathbb{R}$ the function $x \mapsto (\varphi, W_x \varphi)$ converges to zero with $|x| \to \infty$ and $||(\varphi, W_x \varphi)|| = 1$ if $x = 0$. Consequently, the mapping $P^\varphi$ is also open (i.e. any open set is mapped to an open set), hence it is a regular $C^\infty$-embedding of $\mathbb{R}^{2n}$ into $P(\mathcal{H})$; with our choice of $\varphi \in \mathcal{A}_G$, $P^\varphi$ is even an analytic embedding into $P(\mathcal{H})$.

4.1.5. Let $\sigma_j$ denote the vector field on $O_\varphi$ corresponding to the generator $\frac{1}{\hbar}X_j$ ($j = 1, 2, \ldots 2n$). We shall denote by $\Omega^\varphi$ the restriction of the symplectic form $\Omega$ on $P(\mathcal{H})$, 2.2.1, onto $O_\varphi$. The form $\Omega^\varphi$ is nondegenerate, since for the values $\Omega^\varphi_x$ of $\Omega^\varphi$ in any point $\varphi_x \in O_\varphi$ we have:

$$\Omega^\varphi_x(\sigma_j, \sigma_k) = \frac{i}{\hbar^2} Tr(P^\varphi_x[X_j, X_k]) = -\frac{1}{\hbar^2} S_{jk}$$  \hspace{1cm} (4.1.14)

and $\det S = 1$. Hence $M_\varphi = O_\varphi$ in this case. Let $f_{X_j}(x) := f_{X_j}(\varphi_x) := Tr(P^\varphi_x X_j)$ ($x \in \mathbb{R}^{2n}$) be the classical observable corresponding to $X_j$. From (4.1.13) we see, that a unique $\varphi_0 \in O_\varphi$ can be chosen such, that

$$Tr(P^\varphi_0 X_j) = 0 \text{ for all } j = 1, 2, \ldots 2n.$$  \hspace{1cm} (4.1.15)

In the following, we shall take $\varphi := \varphi_0$ according to (4.1.15). Then

$$f_{X_j}(x) = x_j, \quad j = 1, 2, \ldots 2n.$$  \hspace{1cm} (4.1.16)

From (4.1.14) and (4.1.12) we see, that in the coordinates (4.1.16) the form $\Omega^c := \hbar \Omega^\varphi$ is identical with $\Omega^c$ defined earlier. Hence the brackets

$$\{f_{X_j}, f_{X_k}\}(x) := \hbar \Omega^\varphi_x(\sigma_j, \sigma_k) = -S_{jk}$$  \hspace{1cm} (4.1.17)
4.1. THE HEISENBERG GROUP (CCR)

are exactly the **classical Poisson brackets** on $\mathbb{R}^{2n}$, cf. also [31]. The Hamiltonian vector fields on $O_{\varphi}$ corresponding to the Hamiltonian functions $f_{X_j}$ are $\sigma_j$ with flows $\exp(-\frac{i}{\hbar}tX_j)$. This recovers on $O_{\varphi}$ the standard classical kinematics from the geometry of $P(\mathcal{H})$ and the CCR.

4.1.6. Let us look now on the dynamics on $O_{\varphi}$ generated by the Hamiltonian operator

$$A := A_V := \frac{1}{2} \sum_{jk=1}^{n} a_{jk} P_j P_k + V(Q)$$

(4.1.18)

from the point of view of the Sec.3.1 (see (4.1.4) for the notation). Here $a \equiv \{a_{jk}\}$ is a real symmetric positive matrix and $V$ is a real distribution on $\mathbb{R}^n$ chosen such, that the operator $A$ is $\varphi$-classical, Def. 3.3.6. The quantal dynamical group is $\exp(-\frac{i}{\hbar}tA)$ and the corresponding classical projection (= classical mechanical projection) $F^A_t$ on $O_{\varphi}$ is given by the Hamiltonian function

$$f_A(x) := Tr(P_x^\varphi A).$$

(4.1.19)

From (4.1.13) we obtain (with $(q;p) := x$):

$$f_A(q,p) = \frac{1}{2} \sum_{jk=1}^{n} a_{jk} p_j p_k + \text{Tr}(P_{\varphi}V(Q + q)) + \frac{1}{2} \sum_{jk=1}^{n} a_{jk} \text{Tr}(P_{\varphi}P_j P_k),$$

(4.1.20)

where we write $V(Q + q) := W^{-1}_{x} V(Q) W_{x}$. The potential term in the realization (4.1.5) is rewritten as

$$V_{\varphi}(q) := \text{Tr}(P_{\varphi}V(Q + q)) = \int_{\mathbb{R}^n} |\varphi(q')|^2 V(q + q') d^n q',$$

(4.1.21a)

or as a *convolution* ($\tilde{\varphi}(q) := \varphi(-q)$):

$$V_{\varphi}(q) = |\tilde{\varphi}|^2 * V(q) := \varrho_{\varphi} * V(q).$$

(4.1.21b)

This ‘smearing’ of the potential energy by a density $\varrho_{\varphi}$ is the only difference between the classical projections in the case of $G := \text{(the Heisenberg group)}$ and the usual classical limit with the 'unsmeared' potential energy $V(q)$ (up to the unessential additive constant term in (4.1.20)).

4.1.7 Notes. (i) The quantal correlation functions are constant on the orbits $O_{\varphi}$; e.g.

$$\text{Tr}(P_x^\varphi(X_j - x_j)(X_k - x_k)) = \text{Tr}(P_{\varphi}X_j X_k), \text{ for all } j,k, \text{ and for all } x \in \mathbb{R}^{2n},$$

(4.1.22)

(ii) If the Hamiltonian operator $A$ is quadratic in all the generators $X_j$:

$$A := \frac{1}{2} \hbar^{jk} X_j X_k \Rightarrow f_A(x) = \frac{1}{2} \hbar^{jk} x_j x_k + \text{const},$$

(4.1.23)

i.e. in this case the usual classical limit coincides with the classical projections. This situation is analyzed in Sec. 4.2.
4.1.8. On the limit $\hbar \to 0$.

All the previous results and considerations are equally valid for any nonvanishing value of the parameter $\hbar$. Any change of the value of the parameter $\hbar$ might be interpreted from the point of view of mathematics, either as a change of the representation $U_\hbar(G)$ of the Heisenberg group $G$ to an inequivalent one leaving the correspondence of the generators $\frac{1}{\hbar} X_j \in U_\hbar(\mathfrak{g})$ to fixed elements $\xi_j \in \mathfrak{g}$ of the Lie algebra unchanged, or as a change of the basis $\{\xi_j\}$ in $\mathfrak{g}$ into $\{\lambda \xi_j\}$ (corresponding to a 'reinterpretation' (i.e. change of units) of parameters $x$ occurring in (4.1.8)), leaving the choice of the representation fixed.

Let a physical interpretation of the generators $X_j$ be fixed (compare Sec. 1.2), leaving the value of $\hbar$ unspecified. If some empirical system is adequately described by QM with the given interpretation of $X_j$’s, for some value of $\hbar$, then this value $\hbar$ is for the system unique (independently on any choices of generators of the evolution in time - consider, e.g. the occurrence of $\hbar$ in uncertainty relations). If two such systems could form one composite system the mutually noninteracting parts of which they are, then the value of $\hbar$ for both systems is the same (interpretation of $X_j$’s fixed!), since each of the subsystems taken separately determines $\hbar$ for the whole system (we have now a $2(n_1 + n_2) + 1$ -dimensional Heisenberg group, if the subsystems have $n_1$, resp. $n_2$ degrees of freedom).

These considerations show, that any change of the value of $\hbar$ - if physically interpreted - has to be connected with a change of interpretation of the generators $X_j \in U_\hbar(\mathfrak{g})$. We obtain an example of such a reinterpretation, if we describe a system consisting of a large number of particles: in a description of the center of mass motion we can deal instead of center of mass coordinates and total linear momenta (which satisfy CCR with the experimental value of Planck constant) rather with center of mass coordinates and averaged momenta per a particle.

If we keep the interpretation of $X_j$’s fixed, then for various values of $\hbar$ we obtain different theories. We shall describe a transition of $\hbar \to 0$ in the context of the classical projections of QM. Let us write $\lambda^2 \hbar (\lambda \in (0, 1])$ instead of $\hbar$ in all formulas of the subsections 4.1.1 - 4.1.7. Let $X_j(\lambda)$ be the Schrödinger realizations of the CCR-generators in $L^2(\mathbb{R}^n) =: \mathcal{H}$ and let us apply to them the transformation $U_\lambda$ from (4.1.7) for each value of $\lambda$. **Let us denote** $X_j^\lambda := U_\lambda X_j(\lambda) U_\lambda^{-1}$. We obtain:

\[
Q_j^\lambda \varphi(q) = \lambda q_j \varphi(q), \quad P_j^\lambda \varphi(q) = -i \lambda \hbar \frac{\partial}{\partial q_j} \varphi(q),
\]

(4.1.24)

where

\[
Q_j^\lambda := X_j^\lambda, \quad P_j^\lambda := X_{j+n}^\lambda (j = 1, 2, \ldots n).
\]

Let us fix $\varphi = \varphi_0 \in \mathcal{H}$ according to (4.1.15), which will be held unchanged for all the values of $\lambda$. Let $W^\lambda$ be the unitary representation from 4.1.3:

\[
W^\lambda_x := \exp \left( \frac{i}{\lambda^2 \hbar} X^\lambda \cdot S \cdot x \right).
\]

(4.1.25)

Let $\varphi^\lambda_x := W^\lambda_x \varphi$, i.e. for $x := (q; p) \in \mathbb{R}^{2n}$ we have
4.1. The Heisenberg Group (CCR)

\[ \varphi^\lambda_x(q') = \exp \left( -\frac{i}{2\lambda^2}q \cdot p \right) \exp \left( \frac{i}{\lambda} q' \cdot p \right) \varphi(q - \frac{q}{\lambda}); \quad q, p, q' \in \mathbb{R}^n. \]  \quad (4.1.26)

Let

\[ P^{(\lambda)}_x \] be the projector onto \( \varphi^\lambda_x \), \( P^{(\lambda)}_0 = P_\varphi \equiv P_\varphi \) for all \( \lambda \).

The correlations of all orders are for any \( \lambda \) independent of \( x \):

\[ \text{Tr} \left( P^{(\lambda)}_x \left( X^\lambda_j - x_j \right) \left( X^\lambda_k - x_k \right) \ldots \left( X^\lambda_r - x_r \right) \right) = \text{Tr} \left( P_\varphi X^\lambda_j X^\lambda_k \ldots X^\lambda_r \right). \]  \quad (4.1.27)

The right hand side of (4.1.27) is proportional to \( \lambda^s \), where \( s \) is the number of \( X^\lambda \)'s in the right hand side of (4.1.27). From this we see that the algebra \( \mathcal{E}(g)^\lambda \) of quantal observables consisting of polynomials in \( X^\lambda \)'s is mapped onto a set of functions on \( O^\lambda_\varphi := W^\lambda(G)\varphi \):

\[ f^\lambda : E \mapsto f^\lambda_E(x) := \text{Tr} \left( P^{(\lambda)}_x E \right), \quad E \in \mathcal{E}(g)^\lambda; \quad F^\lambda_{X_j}(x) = x_j, \]  \quad (4.1.28)

and this mapping \( f^\lambda \) becomes in the limit \( \lambda \to 0 \) a homomorphism of associative algebras.

For the generator \( f^\lambda \) of the ‘projected’ evolution in time, corresponding to the quantal generator (4.1.18), i.e., for each \( \lambda \), to the operator

\[ A^\lambda := \frac{1}{2} \sum_{jk=1}^n a_{jk} P^\lambda_j P^\lambda_k + V(Q^\lambda), \]  \quad (4.1.29)

we obtain:

\[ f^\lambda (q, p) := \text{Tr} \left( P^{(\lambda)}_x A^\lambda \right) = \frac{1}{2} \sum_{jk=1}^n a_{jk} p_j p_k + \varrho^\lambda \ast V(q) + b_\lambda. \]  \quad (4.1.30)

Here \( b_\lambda \) is a constant depending on \( \lambda \) as \( O(\lambda^2) \) and

\[ \varrho^\lambda(q) := \lambda^{-n} |\varphi(-\frac{q}{\lambda})|^2 \]  \quad (4.1.31)

is a normalized density on \( \mathbb{R}^n \), which weakly converges to the Dirac \( \delta \)-function with \( \lambda \to 0 \). A comparison of flows on \( O^\lambda_\varphi \) (\( = \mathbb{R}^{2n} \)) generated by \( f^\lambda \) for various \( \lambda \) is not easy for given \( V \) and \( \varphi \) in general.

4.1.9. Let \( U^\lambda_A(t) := \exp(-\frac{i}{\hbar} A^\lambda t) \) be the time evolution group corresponding to the generator (4.1.29) (we set \( \hbar = 1 \)). Let

\[ x^\lambda_j(t, x) := \text{Tr} \left( U^\lambda_A(t) P^\lambda_x U^\lambda_A(-t)X^\lambda_j \right) = f^\lambda_{X_j}(U^\lambda_A(t)\varphi^\lambda_x) \]  \quad (4.1.32)

be time-evolved quantal expectations of the ‘canonical’ observables \( X^\lambda_j \) with initial values \( \varphi^\lambda_x \in O^\lambda_\varphi \) (the mapping \( f^\lambda \) from (4.1.28) is here extended to a mapping into functions on \( P(\mathcal{H}) \)).
CHAPTER 4. EXAMPLES OF CLASSICAL MECHANICAL PROJECTIONS

The well-known Ehrenfest’s equations are certain equalities including the functions (4.1.32) and their time-derivatives, which have an analogous form to that of equations of motion of CM, being in the same time exact consequences of QM. We can write them in the form (with \(x^\lambda := (q^\lambda_1, \ldots, q^\lambda_n, p^\lambda_1, \ldots, p^\lambda_n)\) and summation is over 1, 2, \ldots, \(n\)):

\[
\frac{d}{dt}q^\lambda_j(t, x) = a_{jk} p^\lambda_k(t, x) = \frac{\partial}{\partial p_j} f^\lambda_A(x^\lambda(t, x)),
\]

(4.1.33)

\[
\frac{d}{dt}p^\lambda_j(t, x) = -Tr \left( U^\lambda(t) P_x^\lambda U^\lambda(-t) \frac{\partial V}{\partial q_j}(Q^\lambda) \right).
\]

(4.1.34)

Here \(f^\lambda_A\) is the classical Hamiltonian function corresponding to the quantal generator \(A^\lambda\). The corresponding equations for the classical projection on \(O^\lambda\) are of the form:

\[
\frac{d}{dt}q^\lambda_j(t, x)_{cl} = a_{jk} p^\lambda_k(t, x)_{cl} = \frac{\partial}{\partial p_j} f^\lambda_A(x^\lambda(t, x)_{cl}),
\]

(4.1.35)

\[
\frac{d}{dt}p^\lambda_j(t, x)_{cl} = -\frac{\partial}{\partial q_j} \varrho^\lambda(q^\lambda(t, x)_{cl}) = -\frac{\partial}{\partial q_j} f^\lambda_A(x^\lambda(t, x)_{cl}),
\]

(4.1.36)

with \(f^\lambda_A\) from (4.1.30). We shall rewrite (4.1.34) into a form similar to (4.1.36). Let \(y \in \mathbb{R}^{2n}\) and \(W^\lambda_y\) as in (4.1.25). Inserting \(W^\lambda_{-y}\) into the trace in (4.1.34) we obtain:

\[
\frac{d}{dt}p^\lambda_j(t, x) = -\varrho^\lambda(y, t, x) * \frac{\partial V}{\partial q_j}(q^y) = -\frac{\partial}{\partial q_j} \varrho^\lambda(y, t, x) * V(q^y),
\]

(4.1.37)

where \(q^y := (y_1, \ldots, y_n)\) and

\[
\varrho^\lambda(y, t, x)(q) := \frac{1}{\lambda^n} \left| \left( W^\lambda_y U^\lambda(t) W^\lambda_x \varphi \right)(-\frac{q}{\lambda}) \right|^2.
\]

(4.1.38)

Since the right hand side of (4.1.37) is independent of \(y \in \mathbb{R}^{2n}\), we can insert there \(y := x^\lambda(t, x)\) and obtain a formal analogy with (4.1.36). We expect, that the difference \(\varrho^\lambda(y, t, x) - \varrho^\lambda_{\varphi}\) (compare (4.1.21b)) will converge to zero with \(\lambda \to 0\) in the sense of distributions uniformly on compacts in \(t\), if \(y := x^\lambda(t, x)\), and also for \(y := x^\lambda(t, x)_{cl}\), with some reasonable choice of \(V\). This conjecture is based on the results of [154]. (The convergence holds for each fixed \(t \in \mathbb{R}\) for \(y = x^\lambda(t, x)\).\(^1\))

4.1.10 Example. We shall give here an elementary example showing possible differences between a quantal time-evolution and its classical projection. We shall notice also the behaviour of these evolutions in the limit of vanishing \(\lambda\). In the formalism introduced above, let \(\varphi \in L^2(\mathbb{R}, dq)\) represents a ’minimal wave packet’:

\[
\varphi(q) := \pi^{-\frac{1}{4}} \exp(-\frac{1}{2}q^2),
\]

(4.1.39)

\(^1\)This fact was kindly announced to the author by Prof. Klaus Hepp (in 1985).
and choose $\varphi^\lambda := W^\lambda \varphi$ with $z := q - ip$, $W^\lambda_z := \exp[i\lambda^{-2}(Q^\lambda p - P^\lambda q)]$. Let the generator $A^\lambda$ of quantal time-evolution be

$$A^\lambda := a(\lambda)P_\varphi,$$  \hspace{1cm} (4.1.40)

where $a(\lambda)$ is some real function. Then the classical Hamiltonian function on the orbit $O_\varphi^\lambda$ of the Heisenberg group in $L^2(\mathbb{R})$ is

$$f^\lambda_A(z) := \text{Tr}(P^\lambda_z A^\lambda) = a(\lambda) \exp \left(-\frac{zz}{2\lambda^2}\right)$$  \hspace{1cm} (4.1.41)

with $\overline{z}$ being the complex conjugate of $z \in \mathbb{C}$. We are interested in the comparison of solutions of classical Hamiltonian equations on $O_\varphi$, $z^\lambda(t, z)_{cl}$, and the corresponding quantal expectations:

$$z^\lambda(t, z) := \text{Tr}(U^\lambda_A(t)P^\lambda_z U^\lambda_A(-t)Z^\lambda), \quad Z^\lambda := Q^\lambda - iP^\lambda,$$  \hspace{1cm} (4.1.42)

with the same initial values $z = q - ip$. Elementary calculations give:

$$z^\lambda(t, z) = [1 - \frac{1}{a(\lambda)}f^\lambda_A(z)]z + \frac{1}{a(\lambda)}f^\lambda_A(z) \exp(-\frac{it}{\lambda^2}a(\lambda))z,$$  \hspace{1cm} (4.1.43)

$$z^\lambda(t, z)_{cl} = \exp(-\frac{it}{\lambda^2}f^\lambda_A(z))z.$$  \hspace{1cm} (4.1.44)

We see that (4.1.43) and (4.1.44) describe motions on mutually tangent circles in $\mathbb{C}$ with different radii and different dependence of frequencies on initial conditions as well as on the parameter $\lambda$. For $\lambda \to 0$ the quantum evolution vanishes independently on the ‘renormalization’ $a(\lambda)$. For slowly varying $a(\lambda)$, the classical evolution vanishes too, but the way of this vanishing looks qualitatively differently. If, e.g. $a(\lambda) = \lambda^2 \exp(2b\lambda^{-2})$, $b > 0$, then $\overline{zz} = b$ is a critical value for $\lambda \to 0$.

### 4.2 Extension of CCR by a quadratic generator

#### 4.2.1. All the orbits $O_\varphi$ occurring in Sec.4.1 were mutually homeomorphic (and homeomorphic to $\mathbb{R}^{2n}$). In this section, we shall give examples of irreducible representations $U(G)$ of some Lie groups $G$ in a Hilbert space $\mathcal{H}$ containing various mutually nonhomeomorphic orbits $O_j := U(G)\varphi_j$ in $P(\mathcal{H})$, ($j = 1, 2, \ldots$). Let $G$ be a connected Lie group containing the $2n + 1$ - dimensional Heisenberg group $G_n$ as an invariant (i.e. normal) subgroup ($G$ will be specified later). Let $U$ be such a unitary continuous representation of $G$, the restriction of which to $G_n$ coincides with the irreducible representation described in Sec.4.1 with $h = 1 = \lambda$. With the notation of the previous section, for $m = 1, 2, \ldots K$, $A_m \in U(g)$, set

$$A_m := \frac{1}{2} h^m_{jk} X_j X_k, \quad (\text{summation over } j, k = 1, 2, \ldots 2n),$$  \hspace{1cm} (4.2.1)

with any $h_m$ a real symmetric $2n \times 2n$ - matrix; the formally defined operator $A_m$ is symmetric on the Gårding domain of $U(G_n)$. From (4.1.1a) we have commutation relations (cf. also 4.1.3):
\[ [X_j, X_k] = i S_{jk} I, \quad [X_j, A_m] = i S_{jk} h_{m}^k X_l =: i (S \cdot h_m \cdot X)_j, \quad (4.2.2) \]
\[ [A_m, A_k] = \frac{i}{2} X \cdot (h_m \cdot S \cdot h_k - h_k \cdot S \cdot h_m) \cdot X, \quad m, k = 1, 2, \ldots K. \quad (4.2.3) \]

Assume that for any \( m, k \) there are reals \( c_{mk}^j \) such, that
\[ h_m \cdot S \cdot h_k - h_k \cdot S \cdot h_m = \sum_{j=1}^{K} c_{mk}^j h_j, \quad m, k = 1, 2, \ldots K. \quad (4.2.4) \]
then the linear hull of the operators \( X_j \ (j = 1, 2, \ldots 2n) \), \( A_m \ (m = 1, 2, \ldots K) \) and \( I := I_H := id_H \) forms the Lie algebra \( U(\mathfrak{g}) \). We have (cf. also [37, Proposition 3.3.12]):

**4.2.2 Proposition.** Let \( U(\mathfrak{g}) \) be the above defined representation of a Lie algebra \( \mathfrak{g} \) in \( H \) and let \( G \) be the corresponding simply connected Lie group with the Lie algebra \( \mathfrak{g} \). Then the representation \( U(G_n) \) of the Heisenberg group \( G_n \) has a unique extension to the representation \( U(G) \) of \( G \) in \( H \) such, that the closures of the operators \( X_j \ (j = 1, 2, \ldots 2n) \), \( A_m \ (m = 1, 2, \ldots K) \) and \( I_H := id_H \) are selfadjoint generators of \( U(G) \) corresponding to basis vectors in \( \mathfrak{g} \) according to \((2.3.20)\). In particular the operators \( A_m \ (m = 1, 2, \ldots K) \) are essentially selfadjoint on the \( \text{Gårding domain of } U(G_n) \).

**Proof.** The **Gårding domain** of \( U(G_n) \) is a common dense invariant domain of all the operators in \( U(\mathfrak{g}) \). According to a Nelson’s theorem (see [13, Theorem 11.5.2]) it suffices to prove essential selfadjointness of the operator \( \Delta \),
\[ \Delta := \sum_{j=1}^{2n} X_j^2 + \sum_{m=1}^{K} A_m^2, \quad (4.2.5) \]
on the invariant domain. First we shall choose \( m := (j; k) \) with \( j, k = 1, 2, \ldots 2n \) and
\[ A_m := A_{(j;k)} := \frac{1}{2} (X_j X_k + X_k X_j). \quad (4.2.6) \]
In this case the operator \( \Delta \) in \((4.2.5)\) can be expressed in the form
\[ \Delta = \frac{3}{2} n I_H + \sum_{j=1}^{n} (P_j^2 + Q_j^2)(I_H + \sum_{k=1}^{n} (P_k^2 + Q_k^2)), \quad (4.2.7) \]
where we used CCR and the notation \((4.1.4)\). From the known properties of the Hamiltonians \( P_j^2 + Q_j^2 \) of independent linear oscillators, we conclude (with a help, e.g., of [262, Theorem VIII.33]) that \( \Delta \) is essentially selfadjoint.

**Denote the Lie algebra** generated by \( X_j \)'s and \( A_{(j;k)} \ (j, k = 1, 2, \ldots 2n) \) by \( \mathfrak{g}_{\text{max}} \) and the corresponding **simply connected group** by \( G_{\text{max}} \). Any \( A_m \) of the form \((4.2.1)\) is a linear combination of \( A_{(j;k)} \)'s. Consequently, any Lie algebra \( U(\mathfrak{g}) \) from \((4.2.1)\) is a subalgebra of \( U(\mathfrak{g}_{\text{max}}) \) and the corresponding group \( G \) is a subgroup of \( G_{\text{max}} \). From this just proved
4.2. EXTENSION OF CCR BY A QUADRATIC GENERATOR

Integrability of $U(\mathfrak{g}_{\text{max}})$ to a unitary representation $U(G_{\text{max}})$, it follows integrability of $U(\mathfrak{g})$ for any $\mathfrak{g}$ introduced in 4.2.1. This implies the self-adjointness of (4.2.5) with arbitrary $A_m$ of the form (4.2.1) and this, in turn, implies uniqueness of $U(G)$.

4.2.3. In this section we shall restrict our attention to the cases of representations $U(G)$ obtained from $U(G_n)$ by addition of only one generator $A := A_m$ of the form (4.2.1) in the manner described above. Let $h$ be any nonzero real symmetric matrix with elements $h_{jk}$ ($j, k = 1, 2, \ldots 2n$) and let

$$A := \frac{1}{2} h^{jk} X_j X_k$$

(4.2.8)

denote here the self-adjoint operator corresponding to the right hand side of (4.2.8). According to (4.2.6) the operators $X_j$ ($j = 1, 2, \ldots 2n$), $A$ and $I_H$ are self-adjoint generators of an irreducible unitary representation $U(G)$ of a $2n + 2$ dimensional connected Lie group $G$ containing $G_n$ as a normal subgroup. The restriction $U(G_n)$ of $U(G)$ is irreducible, too. Let $U(G)$ be the realization of $G$ in $P(H)$ obtained by the natural projection of $U(G)$, 2.3.9. We shall investigate infinitely differentiable orbits of $U(G)$ in $P(H)$.

4.2.4 Lemma. Let $U(G)$ be as in 4.2.3 and $D_G$ be a dense invariant subset in $H$ consisting of infinitely differentiable vectors of $U(G)$, e.g. $D_G$ is the Gårding subspace for $U(G)([13, 11.1.8])$. Let $\varphi \in D_G$, $\|\varphi\| = 1$ and $O_\varphi := U(G)\varphi$ be the immersed submanifold of $P(H)$ according to 3.1.2. The orbit $O_\varphi$ is $2n$-dimensional iff there is an element $C_\varphi \in U(\mathfrak{g})$,

$$C_\varphi := c^j_\varphi X_j - A$$

(4.2.9)

such, that $\varphi$ is its eigenvector:

$$C_\varphi \varphi = \lambda \varphi \quad \text{for some } \lambda \in \mathbb{R}.$$  

(4.2.10)

If (4.2.9) with (4.2.10) is the case, then $O_\varphi = U(G_n)\varphi$.

Proof. The tangent space to $O_\varphi$ at $\varphi$ is the linear hull of vectors $\sigma_j(\varphi)$ ($j = 1, 2, \ldots 2n$) (see 4.1.5) and $\sigma_A(\varphi)$ (see e.g. 2.3.5 and Sec.3.2). According to 4.1.5, all the $\sigma_j$'s are linearly independent. Hence $O_\varphi$ is $2n$-dimensional iff

$$\sigma_A(\varphi) = c^j_\varphi \sigma_j(\varphi)$$

(4.2.11)

for some reals $c^j_\varphi$. According to (2.3.8), the equation (4.2.10) implies (4.2.11). Assuming (4.2.11), we have in the standard identification of $T_\varphi P(H)$ with $[\varphi]^{\perp}$ by the help of $\Psi_\varphi$ (see 2.1.7 and (2.1.16)):

$$(I - P_\varphi)(c^j_\varphi X_j - A)\varphi = 0 \Rightarrow (c^j_\varphi X_j - A)\varphi = \lambda \varphi$$

(4.2.12)

with $\lambda := \lambda(\varphi) := \text{Tr}(P_\varphi(c^j_\varphi X_j - A))$. 

□
4.2.5 Let \( C := C_\varphi \) have the form (4.2.9) and let (4.2.10) be fulfilled. Then \( C \) satisfies the system of linear equations:

\[
\text{Tr}(P_\varphi[C,X_j]) = 0, \quad j = 1, 2, \ldots 2n, \tag{4.2.13}
\]

\[
\text{Tr}(P_\varphi[C,A]) = 0, \tag{4.2.14}
\]

where (4.2.14) follows from (4.2.13). The equations (4.2.13) have unique solution \( C \) of the form (4.2.9) for any \( \varphi \in D_G \), even if the relation (4.2.10) is not fulfilled:

\[
c^j_\varphi = h^{jk} \text{Tr}(P_\varphi X_k). \tag{4.2.15}
\]

The corresponding operator \( C_\varphi \) represents the generator of the isotropy subgroup \( K_\varphi \subset G \) at the point \( F_\varphi \in g^\ast \) in the \( Ad^\ast(G) \)-representation; here \( F_\varphi(\xi) := \text{Tr}(P_\varphi X_\xi) \) for \( \xi \in g \), compare 3.2.3 and 3.2.6. From (4.2.15) and (4.2.9), we have immediately:

4.2.6 Lemma. If \( \varphi \in O_\varphi \) is chosen such that \( \text{Tr}(P_\varphi X_j) = 0 \) for all \( j = 1, 2, \ldots 2n \), then \( C_\varphi = -A \).

4.2.7 Proposition. The orbit \( O_\varphi \) of \( U(G) \) is 2\( n \)-dimensional iff it contains an eigenprojector \( P_\varphi \) of \( A \), i.e. iff for some \( \varphi \in O_\varphi \) it is

\[
\text{Tr}(P_\varphi A^2) = (\text{Tr}(P_\varphi A))^2. \tag{4.2.16}
\]

Proof. In any orbit lying in \( D_G \) there is a point \( \varphi \) satisfying the conditions of the Lemma 4.2.6, compare 4.1.5. The assertion is an immediate consequence of the Lemmas 4.2.6 and 4.2.4. \( \square \)

4.2.8 Corollaries. (i) Let \( \varphi_0 \in U(G) \varphi \) satisfy (4.1.15). If \( \varphi \) is an eigenvector of \( A \), then also \( \varphi_0 \) is an eigenvector of \( A \), if \( \varphi \in D_G \).

(ii) If \( \varphi_0 \in D_{G_{\text{max}}} \) satisfies (4.1.15), then those relations are satisfied by all the vectors

\[
\varphi^A_t := \exp(-itA)\varphi_0 \tag{4.2.17}
\]

for all \( t \in \mathbb{R} \) and all the choices of \( A \); (4.2.8).

4.2.9 Proposition. For any choice of \( A \) in 4.2.3 there is in \( P(\mathcal{H}) \) a 2\( n \)+1-dimensional orbit of the corresponding representation \( U(G) \) (defined in 4.2.3), which is an infinitely differentiable immersed submanifold of \( P(\mathcal{H}) \).

Proof. Remember that any \( A \) is an unbounded selfadjoint operator. Let \( U_\pi := P_+ - P_- \) be the ‘parity operator’ defined by

\[
U_\pi^* = U_\pi^{-1} = U_\pi, \quad U_\pi X_j U_\pi = -X_j \quad (j = 1, 2, \ldots 2n), \tag{4.2.18}
\]

and \( P_+ \) (resp. \( P_- \)) are corresponding orthogonal projectors,

\[^2\text{In } \mathcal{H} \equiv L^2(\mathbb{R}^n, d^n x), \text{ it is defined as } [U_\pi \psi](x) := \psi(-x), \forall \psi \in \mathcal{H}, \ x \in \mathbb{R}^n.\]
4.2. EXTENSION OF CCR BY A QUADRATIC GENERATOR

\[ P_+ + P_- = I_\mathcal{H}. \]  
(4.2.19)

Choose a dense invariant linear subset \( \mathcal{D}_G \) of \( \mathcal{H} \) consisting of infinitely differentiable vectors of \( U(G) \) such that (as usually)

\[ U_\pi \mathcal{D}_G \subset \mathcal{D}_G, \text{ hence } P_\pm \mathcal{D}_G \subset \mathcal{D}_G. \]  
(4.2.20)

This condition implies that \( P_+ \mathcal{D}_G \) (resp. \( P_- \mathcal{D}_G \)) is dense in \( \mathcal{H}_+ := P_+ \mathcal{H} \) (resp. in \( \mathcal{H}_- := P_- \mathcal{H} \)).

For any \( \varphi \in \mathcal{D}_G^+ \cup \mathcal{D}_G^- \) (with \( \mathcal{D}_G^\pm := P_\pm \mathcal{D}_G \)), the assumption of 4.2.6 is fulfilled due to (4.2.18).

If \( \varphi \) is not an eigenvector of \( A \), then the orbit \( O_\varphi \) is \( 2n+1 \)-dimensional. Assume, that \( A\varphi = \lambda \varphi \).

Let \( \varphi \in \mathcal{D}_G^+ \), for definiteness. Since \( A \) is \( U_\pi \)-invariant: \( [A, U_\pi] = 0 \), its spectral measure \( E_A \) commutes with projectors \( P_\pm \). Denote for any Borel set \( B \subset \mathbb{R} \)

\[ E_A^\pm(B) := P_\pm E_A(B), \text{ hence } E_A = E_A^+ + E_A^-, \]  
(4.2.21)

and \( E_A^\pm \) is the spectral measure of the restriction of \( A \) to the \( U(G) \)-invariant (infinite dimensional) subspace \( \mathcal{H}_+ \) of \( \mathcal{H} \). Due to unboundedness of \( A \), we can assume that the subspace \( (P_+ - E_A^+(\lambda_\lambda))\mathcal{H} \) of \( \mathcal{H}_+ \) is nonempty; here \( E_A^+(\lambda) \) is the eigenprojector of \( P_+ A \) corresponding to the eigenvalue \( \lambda \). Choose a nonzero vector

\[ \varphi' \in (P_+ - E_A^+(\lambda))\mathcal{H} \]  
(4.2.22)

and assume the normalization \( ||\varphi|| = ||\varphi'|| = 1 \). Let \( \chi := \frac{1}{\sqrt{2}}(\varphi' + \varphi) \). Since \( \mathcal{D}_G^+ \) is dense in \( \mathcal{H}_+ \), we can find for arbitrarily small \( \delta > 0 \) a vector \( \varphi_0 \):

\[ \varphi_0 \in \mathcal{D}_G^+ : \ ||\varphi_0 - \chi||^2 < \delta, \ ||\varphi_0|| = 1. \]  
(4.2.23)

With \( \delta < 2 - \sqrt{2} \), the vector \( \varphi_0 \) cannot be an eigenvector of \( A \) and, moreover, it satisfies (4.1.15). Hence the corresponding orbit \( O_{\varphi_0} \) is \( 2n+1 \)-dimensional. The manifold structure was proved in 3.1.2.

\[ 4.2.10. \] Let \( \varphi \in \mathcal{D}_G \) be a \( 2n+1 \)-dimensional orbit of \( U(G) \) and let \( \Omega^\circ \) be the restriction of the standard symplectic form \( \Omega \) on \( P(\mathcal{H}) \) onto \( O_\varphi \), compare 3.2.2. According to the previous results (Sec.’s 3.2 and 4.1), \( \Omega^\circ \) is a closed two-form of the maximal rank \( 2n \), hence it is a contact two-form on \( O_\varphi \) (see, e.g. [1, Chap. 5.1.]).

The equations (4.2.13) determine the characteristic line-bundle of \( \Omega^\circ \) in terms of operators \( C = C_\varphi \) corresponding to generators of stability groups of \( F_\varphi \in \mathfrak{g}^* \) (see 4.2.5) with respect to \( \text{Ad}^* (G) \). The characteristic line bundle of \( \Omega^\circ \) is integrable, determining a regular foliation of \( O_\varphi \). The factorization of \( O_\varphi \) with respect to this foliation is the symplectic manifold \( M_\varphi \) (symplectomorphic to the classical phase space \( T^* \mathbb{R}^n \)) as it was constructed in Sec. 3.2 (for definition of the cotangent bundle \( T^* (M) \) of a general manifold \( M \) see e.g. [37, A.3.6 Definitions (v)]).

\[ 4.2.11. \] The quantal and classical evolutions corresponding to the generator \( A \), cf. 4.2.3, (resp. to the Hamiltonian function \( f_A \)) coincide in our examples in the sense of 3.3.9+3.3.10, independently of the dimension (= \( 2n \) or \( 2n+1 \)) of the orbit \( O_\varphi \). The time-evolved quantal states remain
all the time on the orbit \( O_\varphi \). We might be interested also in time evolution of other quantities than (the expectations of) \( X_j \) in the quantal interpretation. According to 4.1.7(i), in the case of \( \dim O_\varphi = 2n = \dim M_\varphi \), any 'spreading of the wave packet' does not occur. The situation is different, however, on \( 2n+1 \)-dimensional orbits. For various \( \varphi_j \) \((j = 1, 2)\) corresponding to distinct quantal states in the same leaf \([\varphi] \in M_\varphi \) we have in general (cf. 4.1.4 for notation)

\[
\text{Tr}(P^{\varphi_1}(X_j - x_j)(X_k - x_k)) \neq \text{Tr}(P^{\varphi_2}(X_j - x_j)(X_k - x_k)).
\] (4.2.24)

This is the case of e.g., free particle motions. This fact makes a certain difference between classical and quantal interpretations of the 'extended phase spaces' \( O_\varphi \) (\( \dim O_\varphi = 2n + 1 \)). This will be briefly discussed later on, in 4.3.5.

### 4.3 Notes on other examples

#### 4.3.1. By the method developed in our Chap. 3, we can construct from an arbitrary continuous unitary representation \( U(G) \) of a Lie group \( G \) 'classical phase spaces', which are diffeomorphic (and even symplectomorphic) to orbits of \( \text{Ad}^*(G) \). It can be shown, [174, 15.2], that any symplectic homogenous space of any connected Lie group \( G \) is a covering symplectic space of either an orbit of \( \text{Ad}^*(G) \), or an orbit of \( \text{Ad}^*(G_1) \), where \( G_1 \) is a central extension of \( G \) by \( \mathbb{R} \) - see also 1.3.7. On the other hand, unitary continuous representations of \( G \) can be constructed from orbits of \( \text{Ad}^*(G) \), [174]. Considerations in Sec.'s 1.2 and 1.3 show reasons for modeling state spaces of CM-systems as homogeneous symplectic spaces of some Lie groups, at least for 'basic' or 'elementary' physical systems. In this section we shall outline further examples of obtaining CM-systems from unitary group representations which suggest, that all generally accepted models of 'elementary' finite dimensional CM - systems could be obtained in this way.

#### 4.3.2. Classical spin from \( \text{SO}(3) \):

Let \( U \) be a (projective) irreducible representation of the compact Lie group \( \text{SO}(3) \) - the connected component of the 3-dimensional orthogonal group \( \text{O}(3) \) of orthogonal transformations of a 3-dimensional Euclidean space \( E_3 \). The representation space \( \mathcal{H} = \mathbb{C}^{2J+1} \) \((J = \frac{n}{2}, \ n \in \mathbb{Z}_+)\) is finite dimensional. Generators \( Y_k \) \((k = 1, 2, 3)\) of \( U \) corresponding to rotations around orthogonal axes in \( E_3 \) satisfy the commutation relations (with \( \epsilon_{jkm} = -\epsilon_{kjm} = -\epsilon_{jmk}, \ \epsilon_{123} = 1 \)):

\[
[Y_k, Y_m] = i \epsilon_{kmj} Y_j.
\] (4.3.1)

Choose any nonzero \( \varphi \in \mathcal{H} \) and form the orbit \( O_\varphi := \{ U(g)\varphi : g \in \text{SO}(3) \} \). Let us denote by \( Y_\xi \) the generator of \( t \mapsto U(\exp(t\xi)) \) corresponding to an element \( \xi \) of the Lie algebra \( \mathfrak{g} := so(3) \). We are interested in the \( \text{Ad}^*(\text{SO}(3)) \)-action onto \( F_\varphi \in so(3)^* \), where

\[
F_\varphi : \xi \mapsto F_\varphi(\xi) := \text{Tr}(P_\varphi Y_\xi), \ \xi \in so(3).
\] (4.3.2)

Generators \( C_\varphi := c^\varphi_j Y_j \) of one-parameter subgroups of the isotropy group of \( F_\varphi \) are just all nonzero solutions of equations
4.3. NOTES ON OTHER EXAMPLES

\[ \text{Tr}(P_\varphi[Y_k, C_\varphi]) = 0, \quad k = 1, 2, 3. \] (4.3.3)

With \( y^k := y^k(\varphi) := \text{Tr}(P_\varphi Y_k) \), the only linearly independent solution \( C_\varphi \) of (4.3.3) can be written:

\[ C_\varphi = y^k(\varphi)Y_k. \] (4.3.4)

One could easily check that \( C_\varphi = 0 \) in (4.3.4) for some \( \varphi \), iff \( C_\varphi = 0 \) for all \( \varphi \in \mathcal{H} \), iff \( J = 0 \) (i.e. \( \text{dim}_\mathbb{C} \mathcal{H} = 1 \)), iff the matrix of the homogeneous equations (4.3.3) is identically zero. In all other cases the rank of the matrix of the system (4.3.3) equals to 2. For \( J = 0 \) the corresponding classical phase space degenerates to a point: this corresponds to the traditional point of view according to of which spin does not occur in classical mechanics.

For orbits \( O_\varphi \) in representations with \( J \neq 0 \) we have two possibilities:

(i) The vector \( \varphi \) is an eigenvector of \( C_\varphi \) and the orbit \( O_\varphi \) is two-dimensional (any generator \( Y \in U(so(3)) \) which is linearly independent of \( C_\varphi \) cannot be a solution of (4.3.3): \( \text{Tr}(P_\varphi[Y_k, Y]) = 0 \) for \( k = 1, 2, 3 \) implies \( Y = \lambda C_\varphi \); hence \( Y \) linearly independent of \( C_\varphi \) generate two-dimensional tangent space to \( O_\varphi \) at \( \varphi \).

(ii) If \( \varphi \) is not an eigenvector of \( C_\varphi \), then the generator \( C_\varphi \) generates a one-dimensional submanifold of \( O_\varphi \) diffeomorphic to a circle \( S^1 \) (\( C_\varphi \) generates the isotropy subgroup of \( SO(3) \) at \( F_\varphi \), which is closed, hence compact). In this case \( O_\varphi \) is 3-dimensional.

Note that for \( J = \frac{1}{2} \) only the possibility (i) occurs, since \( \mathcal{H} = \mathbb{C}^2 \) and \( \text{dim}_\mathbb{R} P(\mathcal{H}) = 2 \).

It can be easily shown that in the both cases the corresponding classical phase space \( M_\varphi \) (in the case (i) identical with \( O_\varphi \)) is diffeomorphic to the sphere \( S^2 \) in \( so(3)^* \) with coordinates

\[ y^k : F_\varphi \mapsto y^k(\varphi) := \text{Tr}(P_\varphi Y_k), \quad k = 1, 2, 3; \quad \varphi \in O_\varphi. \] (4.3.5)

Let \( t \in \mathbb{R} \) and let \( \tau \in \mathbb{R}^3 \) be any unit vector: \( \sum_k(\tau^k)^2 = 1 \). Let \( y(\varphi) \in \mathbb{R}^3 \) be given by coordinates \( y^k \) in (4.3.5) and \( \tau \cdot y := \sum_k \tau^k y^k \). Using (4.3.1) we obtain:

\[ y^k(\exp(-it\tau^jY_j)\varphi) = y^k(\varphi) \cos t + \epsilon_{kjm} \tau^j y^m(\varphi) \sin t + 2\tau^k \tau \cdot y(\varphi) \sin^2 \frac{t}{2}, \] (4.3.6)

what gives an explicit expression for the sphere \( S^2 \subset so(3)^* \). The \( r_\varphi := \text{radius of the sphere} \) is equal to the length of \( y(\varphi) \),

\[ |y(\varphi)|^2 = y(\varphi) \cdot y(\varphi) = r_\varphi^2. \] (4.3.7)

In the case (i) the values of (4.3.7) might be only the numbers \( J^2, (J-1)^2, (J-2)^2, \ldots \), i.e. the orbits \( O_\varphi \subset P(\mathcal{H}) \) are mapped by the association \( \varphi \mapsto F_\varphi \) (cf. (4.3.2)) onto a finite-number of \( [J+1] \) distinct spheres in the three-dimensional linear space \( so(3)^* \) (here \( [k] \) is the integer part of \( k \in \mathbb{R}_+ \); if \( J \in \mathbb{Z}_+ \) one of the spheres degenerates into a point). But \( P(\mathcal{H}) \) is a connected
manifold and the mapping \( \varphi \mapsto F_\varphi \) is continuous, hence for \( J \geq 1 \) also the cases (ii) occur and the numbers (4.3.7) acquire values from a whole interval of \( \mathbb{R}_+ \), if \( \varphi \) runs over \( P(\mathcal{H}) \).

Let us write explicitly the symplectic form \( \Omega^M \) on the phase space \( M_\varphi = S^2 \). In terms of coordinate functions \( y_k \) from (4.3.5), we obtain in the region where \( y_3(\varphi) \neq 0 \) (indices are written down for convenience):

\[
\Omega^M = -\frac{1}{y_3} \, dy_1 \wedge dy_2, \quad y_3^2 := r_\varphi^2 - y_1^2 - y_2^2.
\]

(4.3.8)

The Poisson bracket of these coordinate functions is

\[
\{y_k, y_m\} = -\epsilon_{kym} y_j.
\]

(4.3.9)

The sphere \( S^2 \) with this symplectic structure is interpreted as the phase space of an (isolated) classical spin. It is an example of a compact symplectic manifold.

4.3.3. We can construct now certain combinations of the previous example with those of Sec.’s 4.1 and 4.2. Let us distinguish generators \( X_j \) of the representation of \( 6N + 1 \) - dimensional Heisenberg group corresponding to coordinates of positions and momenta of \( N \) individual particles. Denote them \( Q^a_j, P^a_j \) \((a = 1, 2, \ldots N; j = 1, 2, 3)\) with CCR in the form

\[
[Q^a_j, P^b_k] = i \, \delta_{ab} \delta_{jk}, \quad [Q^a_j, Q^b_k] = [P^a_j, P^b_k] = 0,
\]

(4.3.10)

for all \( a, b = 1, 2, \ldots N; j, k = 1, 2, 3 \). Now we define operators of orbital momenta (no summation over indices \( a, b \)):

\[
Y^a_j := \epsilon_{jkm} Q^a_k P^a_m, \quad Y^a_j := Y^a_j^{\text{tot}} := \sum_a Y^a_j
\]

(4.3.11)

satisfying (4.3.1) (up to domain specifications) for any upper index \( (a, \text{or} \text{tot}) \). Relations (4.2.2) have now the form:

\[
[Y^a_j, Q^b_k] = i \, \delta_{ab} \epsilon_{jkm} Q^a_m, \quad [Y^a_j, P^b_k] = i \, \delta_{ab} \epsilon_{jkm} P^a_m, \quad [Y^a_j, Y^a_k] = i \, \epsilon_{jkm} Y^a_m.
\]

(4.3.12)

(4.3.13)

Let us first consider the Lie algebra \( \mathfrak{g}_0 \) represented by generators \( Q^a_j, P^a_j \) and \( Y^a_j \) \((j = 1, 2, 3; a = 1, 2, \ldots N)\) of the representation \( U(G_0) \) of the corresponding group \( G_0 \), compare Proposition 4.2.2. We see that \( G_0 \) is a semidirect product of of \( SU(2) \) with the Heisenberg group \( G_{3N} \) (with the notation from 4.2.1), \( G_0 = SU(2) \ltimes G_{3N} \), where the Heisenberg group is a normal subgroup. Let us investigate the orbits \( O_\varphi := U(G_0)\varphi \subset \mathcal{D}_{G_0} \) in \( P(\mathcal{H}) \) and the corresponding classical phase spaces \( M_\varphi \). Since any \( O_\varphi \) is a homogeneous space of \( G_0 \), it can be generated from a point \( \varphi \) satisfying (see 4.1.5)

\[
Tr(P_\varphi X_j) = 0, \text{ for all } j = 1, 2, \ldots 6N.
\]

(4.3.14)
The local structure of $O_{\varphi}$ is most easily seen in a neighbourhood of such $\varphi$. The isotropy group of $F_{\varphi} \in \mathfrak{g}_0$ (see (3.1.5)) with respect to $Ad^*(G_0)$ has the Lie algebra generated by such $C \in U(\mathfrak{g}_0)$, which are solutions of the system

$$Tr(P_{\varphi}[C, X_j]) = 0 \ (j = 1, 2, \ldots 6N), \quad Tr(P_{\varphi}[C, Y_k]) = 0 \ (k = 1, 2, 3). \quad (4.3.15)$$

The corank of the matrix of this homogeneous system is:

(i) equal to 3 iff $Tr(P_{\varphi}Y_k) = 0$ for all $k = 1, 2, 3$; in this situation there might occur cases with $\dim O_{\varphi} = 6N$, $6N + 2$, $6N + 3$ corresponding to such $\varphi$, for which $Y_{\varphi} = 0$ for all $Y \in U(\mathfrak{so}(3))$, (resp. $Y_{\varphi} = 0$ for just one linearly independent $Y \in U(\mathfrak{so}(3))$, resp. $Y_{\varphi} \neq 0$ for all $Y \neq 0$); as an example of the case of $\dim O_{\varphi} = 6N + 3$ we can take $\varphi$ for $N = 1$ in Schrödinger realization of CCR:

$$\varphi(q) := \varphi(q_1, q_2, q_3) := c q_1q_2q_3 \exp(-q_1^2 - q_2^2 - q_3^2), \quad c := \left(\frac{2^5}{\pi}\right)^{\frac{3}{4}}, \quad (4.3.16)$$

corresponding to the value $J = 3$ of the total momentum. In all these cases of various values of $\dim O_{\varphi}$ the corresponding symplectic spaces $M_{\varphi}$ are homeomorphic to $T^*\mathbb{R}^{3N} = \mathbb{R}^{6N}$.

(ii) equal to 1 in all other cases; now all the solutions $C$ of (4.3.15) are proportional to $C_{\varphi}$ of the form (4.3.4). If $\varphi$ is an eigenvector of $C_{\varphi}$, then $\dim O_{\varphi} = \dim M_{\varphi} = 6N + 2$. In the remaining case it is $\dim O_{\varphi} = 6N + 3$ and $\dim M_{\varphi} = 6N + 2$. If $\varphi$ is proportional to $C_{\varphi} \varphi$, the orbit $O_{\varphi}$ is the fiber-bundle with base $\mathbb{R}^{6N}$ and typical fiber $S^2$; if $\varphi$ is not an eigenvector of $C_{\varphi}$, then the fiber on $R^{6N}$ is the whole group $SO(3)$. In the both cases the phase space is $T^*\mathbb{R}^{3N}$ fibered by two dimensional spheres $S^2$ with the canonical symplectic form from $P(H)$ being the sum of the canonical form on $T^*\mathbb{R}^{3N}$ and that on $S^2$ described in (4.3.8).

Let us take now all the operators $Q^a_j$, $P^a_j$, $Y^a_j$ ($a = 1, 2, \ldots N; j = 1, 2, 3$) as generators of the considered representation $U(G)$ (now $G$ is semi direct product of the Heisenberg group $G_{3N}$ and of the direct product of $N$ copies of the group $SU(2)$). The orbits and corresponding phase spaces arising from the action of this group $G$ on $P(H)$ with $H = L^2(\mathbb{R}^{3N}) = L^2(\mathbb{R}^3) \otimes L^2(\mathbb{R}^3) \otimes \ldots L^2(\mathbb{R}^3)$ (N-tuple tensor product) can be constructed as N-tuple direct product manifolds; each of the multiplied manifolds can be obtained by the above described procedure with $N = 1$.

Examples of classical systems obtained in this subsection include systems of several non-relativistic spinning particles. Here the 'classical spin' was obtained from quantal orbital momentum.

4.3.4. The groups which are, perhaps, physically most important ones, are Galilean and Poincaré groups. Because of relative complexity of any complete exposition of these important examples, we shall restrict our present exposition to several notes and remarks. For more detailed nice exposition see e.g. in [321].

(i) The Galilean group.

This group realizes the nonrelativistic (better: Galilean relativistic) conception of relative positions and motions of mechanical systems (particles, bodies etc.). It is a ten parameter Lie group, the parameters of which can be chosen to describe time and space translations.
(4 parameters), space rotations (3 parameters) and transition to uniformly moving systems (3 coordinates of a velocity). Any unitary (vector) representation of this group cannot be, however, interpreted in terms of really observed physical systems, see e.g. [321, Sec.XII.8]. Physically interpreted projective representations correspond to multipliers $m_\tau$ of the Galilean group characterized by a real parameter $\tau$ - the mass of the system. Let us denote by $G$ the central extension (cf. [321, 174], resp. also [37, Note 3.3.6]) of (the covering group of) the Galilean group by $\mathbb{R}$ corresponding to a multiplier $m_\tau$ with $\tau \neq 0$ (all such groups are mutually isomorphic). Orbits of $Ad^*(G)$ (described e.g. in [5]) are just one particle phase spaces obtained in our subsection 4.3.3. Unitary representations of $G$, in which the central subgroup $\mathbb{R}$ acts by a multiplication by constants, correspond to physically interesting projective representations of the Galilean group. Irreducible representations of $G$ describe one-particle systems. The projected orbits $O_\varphi$ of these representations are either seven or nine or ten dimensional (this is a consequence of 4.3.3, 4.2.7 and absolute continuity of the spectrum of the time-evolution generator $P_1^2 + P_2^2 + P_3^2$ of $U(G)$). In the cases $\dim O_\varphi = 7$ or 9 the manifolds $O_\varphi$ with the two-form $\Omega^\circ$ (cf. 3.2.2) are just contact manifolds of the extended phase spaces, $\dim O_\varphi = \dim M_\varphi + 1$.

(ii) The Poincaré group.

Let now $G$ be the ten-parameter covering group of the Poincaré group. Physical interpretation of the parameters is the same as that of the corresponding parameters of the Galilean group. In the present case of $G$, however, the conception of Galilean relativity is replaced by the conception of Einstein relativity of mechanical motions. Since the second cohomology group of $G$ is now trivial, we have to deal with unitary (vector) representations of $G$ only. The orbits of the coadjoint action of $G$ corresponding to phase spaces of particles with nonvanishing masses have the same topological and symplectic structure as in the case (i). The action $Ad^*(G)$ is, however, different from that of the Galilean case; with this are connected also different interpretations of coordinates determined by the mutually corresponding generators in cases (i) and (ii). The dimensionality of orbits $O_\varphi$ of unitary irreducible representations $U(G)$ corresponding to nonzero masses is the same as in (i). Also here, we obtain 7- and 9-dimensional contact manifolds the contact two-form $\Omega^\circ$ on them coincides with the standard two-form of classical relativistic mechanics (which, in the case of $\dim O_\varphi = 7$, comes from the restriction of $dp_\mu \wedge dq^\mu$ defined on $T^*\mathbb{R}^4$ onto the submanifold $p_0^2 - \sum_j p_j^2 = (mass)^2$).

4.3.5 Remark. Any symplectic manifold can be trivially extended to a contact manifold by taking the direct product with $\mathbb{R}$. If $M$ is a symplectic phase space of some physical system, then the added dimension in $\mathbb{R} \times M$ can be interpreted as the ‘time variable’ $t$. Let $\Omega$ be the symplectic form on $M$, $\pi : \mathbb{R} \times M \to M$ be the canonical projection and $\sigma_A$ the Hamiltonian vector field on $M$ with Hamiltonian function $f_A$, i.e. $i(\sigma_A)\Omega = -df_A$. The contact two-forms $\Omega^\circ := \pi^*\Omega$, resp. $\Omega^A := \Omega^\circ - df_A \wedge dt$ on the manifold $\mathbb{R} \times M$ have characteristic vector fields $\delta_t$ (defined by $dt(\delta_t) = 1$ and $df(\delta_t) = 0$ for any function $f$ of the form $f := \pi^*f'$, where $f' \in C^\infty(M)$), resp. $\sigma^A := \pi^*\sigma_A + \delta_t$ (with the identification $T(\mathbb{R} \times M) = T\mathbb{R} \times TM$ in the sense of vector bundle isomorphisms). Clearly $\pi_*\sigma^A = \sigma_A$. For a time-independent vector field $\sigma_A$ this procedure is trivial, if we have no possibility to distinguish various points of the fibres $\mathbb{R} = \pi^{-1}(x) \ (x \in M)$ by some measurements, i.e. if time is homogeneous with respect to the
4.3. NOTES ON OTHER EXAMPLES

This is the case of classical mechanics determined by $(M;\Omega)$ and $f_A \in C^\infty(M)$.

The situation is different for contact orbits $O_\varphi \subset P(\mathcal{H})$. Each point of $O_\varphi$ corresponds to a quantum mechanically clearly distinguishable physical state: by measuring of also quantities other than expectations of generators of $U(G)$, we can empirically distinguish various points of the same fibre, on which all the expectations of the generators in $U(g)$ are constant. This fact breaks, in a certain sense, the homogeneity of time on contact orbits of the representations, which contain also time evolution of the system as a one parameter subgroup.

4.3.6. Identical particles.

If the physical system consists of $N$ mutually distinguishable, but otherwise equal subsystems, it is described in QM by the $N$-fold tensor product Hilbert space $\mathcal{H}_N := \mathcal{H} \otimes \mathcal{H} \otimes \cdots \otimes \mathcal{H}$ with the Hilbert space $\mathcal{H}$ describing a single subsystem. If the 'basic observables' of a single subsystem are determined by a representation $U(G)$ in $\mathcal{H}$, observables of the whole compound system might be determined by the representation $U_N$ of the $N$-fold direct product group $G_N := G \times G \times \cdots \times G$, i.e. for $\varphi := \varphi_1 \otimes \varphi_2 \otimes \cdots \otimes \varphi \in \mathcal{H}_N$, $\varphi_j \in \mathcal{H}$, we set 

$$U_N(g_1 \times g_2 \times \cdots \times g_N)\varphi := U(g_1)\varphi_1 \otimes U(g_2)\varphi_2 \otimes \cdots U(g_N)\varphi_N$$

for all $g_j \in G$, and extend $U_N$ onto $\mathcal{H}_N$ by linearity and continuity. This is the case of, e.g., the example in Sec.4.1. Then we can construct in the usual way orbits $O_\varphi := U_N(G_N)\varphi$ in $P(\mathcal{H}_N)$ and corresponding symplectic manifolds $M_\varphi$. We shall write also $U(G_N) := U_N(G_N)$.

In physics, however, 'equal (micro-)subsystems' are indistinguishable. If the $N$ subsystems are indistinguishable (identical), then for any permutation $\pi \in \Pi_N$ (:= the permutation group of $N$ elements) the product-vectors $\varphi := \varphi_1 \otimes \varphi_2 \otimes \cdots \otimes \varphi_N$ and $\pi \cdot \varphi := \varphi_{\pi(1)} \otimes \varphi_{\pi(2)} \otimes \cdots \otimes \varphi_{\pi(N)}$, as well as their linear combinations (the permutations $\pi \in \Pi_N$ act here also as linear operators on $\mathcal{H}_N$) are physically indistinguishable. There were discovered in the particle and statistical physics two kinds of particles: Bose particles - bosons (e.g. photons, mesons) specified by their integer particle spin, and Fermi particles - fermions (e.g. electrons, protons, neutrinos) having half-integer spins. Collections of $N$ identical particles of each of these kinds behave according of their own specific 'statistics': Bose, resp. Fermi statistics. The two 'statistics' are formalized by two different symmetry properties of multiparticle wave functions of corresponding collections of particles. In the case of Bose (resp. Fermi) statistics the only physically realizable states correspond to totally symmetric (resp. totally antisymmetric) vectors $\varphi \in \mathcal{H}_N$:

$$\pi \cdot \varphi = \epsilon_+(\pi)\varphi, \quad \epsilon_+(\pi) := 1, \quad \text{for all } \pi \in \Pi_N,$$

(4.3.17a)

in the case of Bose statistics, resp.

$$\pi \cdot \varphi = \epsilon_-(\pi)\varphi, \quad \epsilon_-(\pi) := \pm 1 := \text{parity of } \pi \in \Pi_N.$$

(4.3.17b)

in the case of Fermi statistics.\(^3\)

Let $P_+$ (resp. $P_-$) be the orthogonal projector in $\mathcal{H}_N$ onto the subspace $\mathcal{H}_N^+$ (resp. $\mathcal{H}_N^-$) of the totally symmetric (4.3.17a) (resp. totally antisymmetric (4.3.17b)) vectors. Now we intend

\(^3\)This relation between spin and statistics can be obtained as a consequence of mathematical axiomatics of relativistic quantum field theory, cf. e.g. [301].
to project the above mentioned orbits $O_\varphi \subset P(\mathcal{H}_N)$ into $P(\mathcal{H}_N^+)$, resp. into $P(\mathcal{H}_N^-)$. To make the procedure more transparent we shall divide it to more steps then it is, perhaps, necessary. For a $U(G_N)$-analytic vector $\varphi \in \mathcal{H}_N$ ($\varphi \neq 0$) let $\tilde{O}_\varphi := U(G_N)\varphi$, so that $O_\varphi := P\tilde{O}_\varphi$.

We shall denote by $P: \mathcal{H}' \to P(\mathcal{H}')$, $\varphi \mapsto P_\varphi$, the natural projection in all the cases of $\mathcal{H}' := \mathcal{H}_N$, $\mathcal{H}_N^+$, $\mathcal{H}_N^-$. Let

$$\tilde{O}_\varphi^+ := P_+\tilde{O}_\varphi, \quad \tilde{O}_\varphi^- := P_-\tilde{O}_\varphi \text{ be subsets of } \mathcal{H}_N^+ \text{ (resp. } \mathcal{H}_N^-). \quad (4.3.18)$$

Assume, for definiteness, that $P_+\varphi \neq 0$, and concentrate ourselves to the Bosonic case (the formal procedures are similar with the fermions). Let $K^\varphi$ be the stability group of $\varphi$ with respect to $U(G_N)$. Considerations similar to those of Sec.3.1 show that $\tilde{O}_\varphi$, as an immersed submanifold of $\mathcal{H}_N$, is diffeomorphic to $G_N/K^\varphi$. We shall consider $\tilde{O}_\varphi$ with the differentiable manifold structure of $G_N/K^\varphi$. The restricted mapping of $P_+$:

$$P^\varphi_+ : \tilde{O}_\varphi \to \mathcal{H}_N^+, \quad \psi \mapsto P_+\psi, \quad \psi \in \tilde{O}_\varphi, \quad (4.3.19)$$

is (infinitely) differentiable. Hence the set

$$\tilde{O}_\varphi^\varphi := (P^\varphi_+)^{-1}(0) \subset \tilde{O}_\varphi \quad (4.3.20)$$

is closed in $\tilde{O}_\varphi$, and

$$\tilde{O}_\varphi^\varphi := \tilde{O}_\varphi \setminus \tilde{O}_\varphi^\varphi \text{ is a submanifold of } \tilde{O}_\varphi.$$ Each point of $P^\varphi_+\tilde{O}_\varphi^\varphi$ has a well defined projection into $P(\mathcal{H}_N^+)$ and the mapping $PP^\varphi_+$,

$$PP^\varphi_+ : \tilde{O}_\varphi^\varphi \to P(\mathcal{H}_N^+), \quad \varphi' \mapsto PP^\varphi_+\varphi' := \{\lambda P^\varphi_+\varphi' : \lambda \in \mathbb{C}\} \in P(\mathcal{H}_N^+), \quad (4.3.21)$$

is real analytic. The number $rg(\varphi') \in \mathbb{Z}_+$ ($\varphi' \in \tilde{O}_\varphi^\varphi$):

$$rg(\varphi') := \text{rank } T_{\varphi'}(PP^\varphi_+), \quad (4.3.22)$$

where $T_{\varphi'}$ is the tangent mapping in an arbitrarily chosen point $\varphi' \in \tilde{O}_\varphi^\varphi$, is given in some charts on $\tilde{O}_\varphi^\varphi$ around $\varphi'$ and on $P(\mathcal{H}_N^+)$ around $PP^\varphi_+\varphi'$ as the dimension of the vector space

$$T_{\varphi'}(PP^\varphi_+)[T_{\varphi'}\tilde{O}_\varphi^\varphi] \text{ (which is, roughly speaking, the maximal rank of submatrices of the mapping } T_{\varphi'}(PP^\varphi_+) \text{ in these charts with nonvanishing determinants).}$$

The function $\varphi' \mapsto rg(\varphi')$ is lower semicontinuous, and possesses only finite number of values. Hence for $m_\varphi := \max\{rg(\varphi') : \varphi' \in \tilde{O}_\varphi^\varphi\}$ the subset $\tilde{O}_\varphi^m_\varphi$ of $\tilde{O}_\varphi$ defined by:

$$\tilde{O}_\varphi^m_\varphi := rg^{-1}(m_\varphi) := \{\varphi' \in \tilde{O}_\varphi^\varphi : rg(\varphi') = m_\varphi\}, \quad (4.3.23)$$

is open, hence it is a submanifold of $\tilde{O}_\varphi$. We can assume that $\varphi$ was chosen such, that $\varphi \in \tilde{O}_\varphi^m_\varphi$. Let, for any $\psi \in \tilde{O}_\varphi^m_\varphi$, the $t^\psi_0 \subset \mathfrak{g}_N$ ($:= \text{the Lie algebra of } G_N$) be the linear space consisting of those generators $\xi \in \mathfrak{g}_N$ for which

\[\text{This vector space is, as could be seen from the formula, the image of the tangent space } T_{\varphi'}\tilde{O}_\varphi^\varphi \text{ by the tangent map of the mapping } PP^\varphi_+.\]
4.3. NOTES ON OTHER EXAMPLES

\[ T_\psi(PP^+_\varphi)X_\xi \psi := i \frac{d}{dt} \bigg|_{t=0} PP^+_\varphi \exp(-itX_\xi)\psi = 0. \tag{4.3.24} \]

Clearly, \( \dim \psi_0^\varphi = \dim G_N - m_\varphi \) is constant for all \( \psi \in \widetilde{O}^m_{\varphi^+} \). The equation 4.3.24 is equivalent to the equation

\[ (I_\mathcal{H} - P_{\psi(\cdot)^+})P_+X_\xi \psi = 0, \text{ with } \psi^{(+)} := P^\varphi_+\psi. \tag{4.3.25} \]

By the relation \( \psi^{(\pm)} \in \mathcal{H}^\mp_N \) is defined the completely symmetric (resp. antisymmetric) part of the vector \( \psi \in \mathcal{H}_N \). Let

\[ m_0^\varphi \text{ be a complementary subspace in } \mathfrak{g}_N \text{ to } \mathfrak{e}^\varphi. \]

Since the mapping \( PP^\varphi_+ \) restricted to \( \widetilde{O}^m_{\varphi^+} \) is smooth and of constant rank \( m_\varphi \), it is a subimmersion (compare [51, 5.10.6.]), hence there is a manifold \( Z^m_{\varphi^+} \) of dimension \( m_\varphi \) and a submersion \( s^\varphi_+: \widetilde{O}^m_{\varphi^+} \to Z^m_{\varphi^+} \) as well as an immersion \( \iota^\varphi_+: Z^m_{\varphi^+} \to P(\mathcal{H}^+_N) \) such that

\[ PP^\varphi_+(\widetilde{O}^m_{\varphi^+}) = \iota^\varphi_+(Z^m_{\varphi^+}). \tag{4.3.26a} \]

This means, that the image \( PP^\varphi_+(\widetilde{O}^m_{\varphi^+}) \subset P(\mathcal{H}^+_N) \) can be considered as an immersed submanifold (with possible selfintersections) of \( P(\mathcal{H}^+_N) \):

\[ PP^\varphi_+(\widetilde{O}^m_{\varphi^+}) = \iota^\varphi_+(Z^m_{\varphi^+}). \tag{4.3.26b} \]

A basis of the tangent space to \( Z^m_{\varphi^+} \) is generated in the point \( \nu := s^\varphi_+(\varphi) \) by curves \( t \mapsto s^\varphi_+(\exp(-itX_\xi)\varphi) \) with \( \xi \in m_0^\varphi \). The image by \( T_\varphi \iota^\varphi_+ \) of this tangent space in \( T_{\varphi^{(+)}}P(\mathcal{H}^+_N) \) is generated by vectors which, in the chart \( \Psi_{\varphi^{(+)}} \) (see 2.1.5, 2.1.8), have the form

\[ T_{\varphi^{(+)}}\Psi_{\varphi^{(+)}}(v_\xi) := -i(I - P_{\varphi^{(+)}})P_+X_\xi \varphi, \quad \xi \in m^\varphi_0. \tag{4.3.27} \]

The values of the symplectic form \( \Omega \) on \( P(\mathcal{H}^+_N) \) on these vectors are:

\[ \Omega_{\varphi^{(+)}}(v_\eta, v_\xi) = -2\|\varphi^{(+)}\|^{-2} \text{Im}(P_+X_\eta\varphi, (I - P_{\varphi^{(+)}})P_+X_\xi \varphi). \tag{4.3.28} \]

The pull-back of \( \Omega \) by \( \iota^\varphi_+ \) makes \( Z^m_{\varphi^+} \) a manifold endowed with a canonical two-form. It is known, that the factorization of the subimmersion \( PP^\varphi_+ \) (together with the choice of the manifold \( Z^m_{\varphi^+} \)) can be chosen in a canonical way, see [51, 5.10.7]. We assume here, that the mapping \( s^\varphi_+ \) is onto (i.e. surjective), what is possible, because any submersion is an open mapping. The form \( \iota^\varphi_+^* \Omega \) on \( Z^m_{\varphi^+} \) is closed. The subset of \( Z^m_{\varphi^+} \) on which the form \( \iota^\varphi_+^* \Omega \) has its maximal rank is an open set, hence a submanifold \( Z_{\varphi^+} \) of \( Z^m_{\varphi^+} \). Denote by \( \Omega^\varphi_+ \) the restriction of \( \iota^\varphi_+^* \Omega \) onto \( Z_{\varphi^+} \). Since \( d\Omega^\varphi_+ = 0 \), the characteristic bundle of \( \Omega^\varphi_+ \) (consisting of vector fields on \( Z_{\varphi^+} \) annihilating the form \( \Omega^\varphi_+ \)) is an integrable subbundle of \( TZ_{\varphi^+} \), see e.g. [1, 5.1.2], determining a natural foliation of \( Z_{\varphi^+} \); any leaf of this foliation is an immersed connected submanifold of \( Z_{\varphi^+} \). Let \( M^\varphi_+ \) be the factor space obtained from \( Z_{\varphi^+} \) by its decomposition into the leaves of this foliation and let \( p^+_M : Z_{\varphi^+} \to M^\varphi_+ \) be the natural projection. If the equivalence relation on
CHAPTER 4. EXAMPLES OF CLASSICAL MECHANICAL PROJECTIONS

Z_{\varphi^+} given by classes identical with leaves \([p_M^+]^{-1}(x) (x \in M_{\varphi}^+)\) is regular (see [51, 5.9.5]), then there is unique manifold structure on \(M_{\varphi}^+\) such that \(p_M^+\) is a submersion. In this case there is, on the manifold \(M_{\varphi}^+\), a unique symplectic form \(\Omega^M_{\varphi^+}\) satisfying

\[ p_M^{++}{\Omega^M_{\varphi^+}} = \Omega^0_{\varphi^+}. \] (4.3.29)

The Proposition 3.2.10 is a special case of this assertion.

Note: In the above presented construction of the symplectic manifold \((M_{\varphi}^+, \Omega^M_{\varphi^+})\), we did not use any specific properties of the projector \(P_+\) and of the group action \(U(G_N)\). These properties enter in constructions of specific orbits.

4.3.7. We shall specify here the previous construction to the case of \(G_N := N\)-fold direct product of \(2n+1\)-dimensional Heisenberg group \(G\) with infinite-dimensional unitary irreducible representations \(U\) in \(\mathcal{H}\). The linear space \(U_N(\mathfrak{g}_N)\) is spanned by elements\(^5\)

\[ X_{\xi} := \sum_{j=1}^{N} X_{\xi}^j \quad \text{with any } X_{\xi}^j \in U(\mathfrak{g}), \xi \in \mathfrak{g}_N, \] (4.3.30)

where the index \(j\) has the following meaning: If \(\varphi \in \mathcal{H}_N\) has the form

\[ \varphi := \varphi_1 \otimes \varphi_2 \otimes \cdots \otimes \varphi_N, \] (4.3.31)

then the linear operator \(X^j\) on \(\mathcal{H}_N\) corresponds to an (equally denoted) operator on \(\mathcal{H}\) by:

\[ X^j_{\varphi} := \varphi_1 \otimes \varphi_2 \otimes \cdots \otimes X^j \varphi_j \otimes \varphi_{j+1} \otimes \cdots \otimes \varphi_N. \] (4.3.32)

(No summation! In this subsection all sums are explicitly indicated.)

Let us work in the Schrödinger realization of CCR, i.e. \(\mathcal{H} = L^2(\mathbb{R}^n), \mathcal{H}_N = L^2(\mathbb{R}^{nN})\) and operators \(X^k_j (k = 1, 2, \ldots N; j = 1, 2, \ldots 2n)\) acting on the \(k\)-th copy of \(L^2(\mathbb{R}^n)\) are chosen as in (4.1.5). Let \(\varphi \in \mathcal{H}_N\) be given by (4.3.31) with \(\varphi_j \in L^2(\mathbb{R}^n)\), \(\text{supp } \varphi_j \cap \text{supp } \varphi_k = \emptyset (j \neq k)\) and such, that there is a neighbourhood of unity \(e \in G\) so that for any \(g_j (j = 1, 2, \ldots N)\) in this neighbourhood also \(U(g_j)\varphi_j\) and \(U(g_k)\varphi_k\) \((j \neq k)\) have disjoint supports. We assume, moreover, that \(\varphi\) is a smooth function on \(\mathbb{R}^{nN}\). With these assumptions, we obtain from (4.3.28) in a neighbourhood of the point \(s^\varphi_{\pm}(\varphi)\) on \(Z^{n}_{\varphi^\pm}\) (the following result shows that the mappings \(PP^\varphi_{\pm}\) have at \(\varphi\) the maximal rank):

\[ \Omega_{\varphi(\pm)}(v_\eta, v_\xi) = i \sum_{j=1}^{N} \left(\varphi_j, [X^j_{\eta}, X^j_{\xi}]\varphi_j\right), \] (4.3.33)

where we assumed for all the \(j: \|\varphi_j\| = 1\), and \(X^j_\eta, X^j_\xi\) in (4.3.28) are of the form (4.3.30).

The expression (4.3.33) shows, that \(Z_{\varphi^\pm} = M_{\varphi^\pm}\) is a \(2Nn\)-dimensional symplectic manifold. This means, that \(Z_{\varphi^\pm}\) for both signs are locally diffeomorphic (and symplectomorphic) to

\(^5\)For \(\mathfrak{g}_N = \bigoplus_{j=1}^{N} \mathfrak{g}^{(j)}, \mathfrak{g}^{(j)}\) are copies of \(\mathfrak{g}\), one has \(\xi := \sum_{j=1}^{N} \xi_j\) with \(\xi_j \in \mathfrak{g}^{(j)}, X^j_\xi := X^j_{\xi} \in U(\mathfrak{g}).\)
4.3. NOTES ON OTHER EXAMPLES

$M_\varphi = O_\varphi = \mathbb{R}^{2Nn} \subset P(H_N)$ (Section 4.1). In a neighbourhood of $\varphi' \in O_\varphi$, the functions $\varphi' \mapsto \text{Tr}(P_\varphi X_k^j)$ ($j = 1, 2, \ldots; k = 1, 2, \ldots; 2n$) are symplectic coordinates. Similarly, in a neighborhood of $s_\pm^\varphi(\varphi)$ the functions

$$f_k^j : s_\pm^\varphi(\varphi') \mapsto \text{Tr}(P_\varphi X_k^j) = (\varphi'_j, X_k^j \varphi'_j), \quad j = 1, 2, \ldots; k = 1, 2, \ldots; 2n,$$  \hspace{1cm} (4.3.34)

are symplectic coordinate functions on $Z_{\varphi \pm}$.

Let us assume now, that $\varphi_j$'s in (4.3.31) have the form

$$\varphi_j := W_{x^{(j)}} \varphi_0 \text{ for some } \varphi_0 \in L^2(\mathbb{R}^n), \quad x^{(j)} \in \mathbb{R}^n,$$  \hspace{1cm} (4.3.35)

assuming $\varphi_0$ to be smooth with compact support, and $x^{(j)} \neq x^{(k)}$ ($j \neq k$) such that $\varphi_j, \varphi_k$ have mutually disjoint supports, see 4.1.3 for the notation. On the orbit $O_\varphi$ in $H_N$, there is also the point

$$(\otimes \varphi_0)^N := \varphi_0 \otimes \varphi_0 \otimes \cdots \otimes \varphi_0.$$  \hspace{1cm} (4.3.36)

Choose now $\varphi$ equal to (4.3.36) and calculate the values of (4.3.28) in the points $\varphi_{\pm} \in P(H_N^0)$. In the antisymmetric case we obtain zero, since $P_{-} \varphi =: \varphi_{-} = 0$ (hence $\varphi \in \overset{\sim}{O}_{\varphi_{-}}$, (4.3.20), and $PP_{-} \varphi$ is not defined).

In the case of Bose statistics we have:

$$\Omega_{\varphi(\pm)}(v_\eta, v_\xi) = \frac{i}{N} \sum_{j=1}^{N} \sum_{k=1}^{N} (\varphi_0, [X_{\eta}^k, X_{\xi}^j]) \varphi_0,$$  \hspace{1cm} (4.3.37)

where $X_{\eta}^j$ ($j = 1, 2, \ldots; N$) should be considered as operators in $L^2(\mathbb{R}^n)$, ignoring the definition (4.3.32): they act on $L^2(\mathbb{R}^n)$ regardless of its order in the tensor product forming the whole Hilbert space $H_N$. The rank of the form (4.3.37) equals to $2n$ and the point $PP_{\pm}^\varphi(\varphi)$ does not belong to $i_\varphi^\varphi(Z_{\varphi_{+}})$ for $N \geq 2$, i.e. $\varphi$ is not mapped by $s_\varphi^\varphi$ into the symplectic manifold $Z_{\varphi_{+}}$. We see that, although locally symplectomorphic to $R^{2Nn}$, the both classical phase spaces $Z_{\varphi_{-}}$ and $Z_{\varphi_{+}}$ of identical particles are globally different from the standard cotangent bundle $T^*\mathbb{R}^{2Nn}$: in classical projections the Pauli exclusion principle holds for identical particles, regardless to the kind of their statistics.

4.3.8. With the notation from 4.3.6, let $V_N(G)$ be the unitary representation of $G$ in $H_N$ (reducible for $N \geq 2$) defined as the diagonal part of $U_N$:

$$V_N(g) := U_N(g \times g \times \cdots \times g), \quad \text{for all } g \in G.$$  \hspace{1cm} (4.3.38)

The Lie algebra $V_N(\mathfrak{g})$ is generated by the basis of the form (4.3.30) with $X_{\xi}^j = X_{\xi}^k$ (considered as operators in $H$) for all $j, k = 1, 2, \ldots; N$, $\xi \in \mathfrak{g}$. Such operators $X_{\xi} \in V_N(\mathfrak{g})$ commute with projectors $P_\pm$. Hence $V_N$ leaves the subspaces $H_N^+_N$ and $H_N^-_N$ invariant, and we can obtain the classical projections of this 'macroscopic' (for large $N$) subsystem in the standard way, (Sec.3.2); the obtained classical phase spaces are orbits of $Ad^*(G)$ with their canonical
symplectic structure - there is no difference in the kinds of statistics, from the point of view of kinematics.

In trying to extend our constructions to systems consisting of infinite number $N \to \infty$ of equal (or identical) subsystems, we meet the problems of divergence of 'global (or collective) observables' $X^N_\xi := X_\xi$ and of discontinuity of the resulting representation $V_\infty$ of $G$. We give a formalization of this 'large $N$ limit' in the next Section 5.1, and in the Sec. 5.2 we outline a possible generalization of obtaining classical subsystems of collective observables from infinite quantal systems. We shall not take any care of statistics of subsystems, what could be motivated by results of the last two subsections: the statistics seems to have no essential influence upon the classical phase spaces of systems of identical particles.
Chapter 5

Macroscopic limits

5.1 Multiple systems

5.1.1. We shall construct in this section classical subsystems of a large quantal system. We shall assume here that the large system consists of infinite number of copies of a finite subsystem of the type dealt with in preceding sections. The infinite "macroscopic" system is obtained as an inductive limit of a net of systems consisting of an increasing number of copies of the mentioned finite systems. The symmetry group $G$ of a single finite subsystem is then also a symmetry group of the large system. An essential formal difference with respect to the systems discussed in preceding sections is that the action of $G$ on the large system is not described by a continuous unitary representation, hence we cannot introduce generators corresponding to one-parameter subgroups of $G$ as operators in some Hilbert space.

5.1.2. To make the following considerations more intuitive, let us come back for a while to finite systems consisting of $N$ equal subsystems. Let the unitary representation $V_N(G)$ and its generators $X_N^\xi := X_\xi$ ($\xi \in \mathfrak{g}$) be defined as in 4.3.3, resp. in (4.3.30). Then

$$[X_N^\xi, X_N^\eta] = i X_N^{[\xi,\eta]} \quad (\xi, \eta \in \mathfrak{g}) \quad (5.1.1)$$

and the restriction to the orbit $O^N_\varphi := V_N(G)\varphi \,(\varphi \in \mathcal{H}_N)$ of the canonical symplectic form $\Omega^N$ on $P(\mathcal{H}_N)$ is determined by

$$\Omega^N_\varphi(\sigma_\xi, \sigma_\eta) = i Tr(P_\varphi[X_N^\xi, X_N^\eta]), \quad (\xi, \eta \in \mathfrak{g}). \quad (5.1.2)$$

Here $\sigma_\xi$ is the vector field on $P(\mathcal{H}_N)$ corresponding to the unitary flow

$$(t; \varphi) \mapsto \exp(-itX_N^\xi)\varphi, \quad \varphi \in \mathcal{H}_N, \quad t \in \mathbb{R}. \quad (5.1.3)$$

For $N \to \infty$, the operators $X_N^\xi$ diverge and $V_N(G)$ does not converge to any continuous unitary representation - compare the next subsection. Let

$$X_{\xi N} := \frac{1}{N} X_N^\xi, \quad \xi \in \mathfrak{g}, \quad N = 1, 2, \ldots \quad (5.1.4)$$
CHAPTER 5. MACROSCOPIC LIMITS

In terms of \([155]\) \(X_\xi^N\) (resp. \(X_{\xi N}\)) are ‘extensive (resp. intensive) observables’ but, contrary to [155], they can be unbounded in our case. The limits for large \(N\) of \(X_{\xi N}\)’s could exist in some convenient sense, but they are not generators of any unitary representation of the group \(G\). Due to the commutation relations

\[
[X_{\xi N}, X_{\eta N}] = \frac{i}{N} X_{[\xi,\eta] N}, \tag{5.1.5}
\]

the limits of \(X_{\xi N}\) \((\xi \in \mathfrak{g})\) will be mutually commuting operators. To obtain correct classical commutation relations (i.e. the Poisson brackets, see 1.3.5) for functions \(f_{\xi N}\) on the orbits \(O_x^N (x \in \mathcal{H}_N)\),

\[
f_{\xi N} : x \mapsto f_{\xi N}(x) := Tr(P_x X_{\xi N}), \tag{5.1.6}
\]

in the limit \(N \to \infty\), the two-form \(\Omega^N\) from (5.1.2) should be ‘renormalized’. We define

\[
\Omega_N := \frac{1}{N} \Omega^N. \tag{5.1.7}
\]

The form \(\Omega_N\) (if restricted onto the symplectic manifold \(M_x^N\) obtained from \(O_x^N\) as in Sec.3.2) associates with the Hamiltonian function \(f_{\xi N}\) the vector field \(\sigma_\xi\) (restricted to \(M_x^N\)) given by the flow (5.1.3). It is

\[
\Omega_N(\sigma_\xi, \sigma_\eta) = i Tr(P_\bullet [X_{\xi}^N, X_{\eta}^N]) = -Tr(P_\bullet X_{[\xi,\eta] N}). \tag{5.1.8}
\]

We intend to develop a corresponding formalism for infinite systems, i.e. a suitable one for the work in the limit \(N = \text{‘actual infinity’}\).

5.1.3. Let \(U(G)\) be a continuous unitary representation of a connected Lie group \(G\) on a separable Hilbert space \(\mathcal{H}\). We shall use notation of Chap. 4 for concepts related to \(U(G)\). Let \(\Pi\) be an index set (of arbitrary cardinality) and \(\mathcal{H}_j (j \in \Pi)\) be copies of \(\mathcal{H}\). Let us fix unitary maps

\[
u_j : \mathcal{H} \to \mathcal{H}_j, \quad j \in \Pi, \tag{5.1.9}
\]

of \(\mathcal{H}\) onto \(\mathcal{H}_j\)’s. Let

\[
\mathcal{H}_\Pi := \bigotimes_{j \in \Pi} \mathcal{H}_j \tag{5.1.10}
\]

be the tensor product defined according to von Neumann [227] and known as \(CTPS (:= \text{complete tensor product space})\) - see also notes in the text in 5.1.4 below and [106, 274, 35]). For \(\varphi_j \in \mathcal{H}_j\) let

\[
\Phi := \bigotimes_{j \in \Pi} \varphi_j \tag{5.1.11}
\]
be a product-vector in \( \mathcal{H}_\Pi \). For any linear densely defined operator \( A \) on \( \mathcal{H} \) (with domain \( D(A) \subset \mathcal{H} \)) and for \( \varphi_j \in \mathcal{H}_j \) such that \( u_j^{-1}\varphi_j \in D(A) \) let \( \pi_j(A) \) be the operator on \( \mathcal{H}_\Pi \) determined by

\[
\pi_j(A)\Phi := \bigotimes_{k \in \Pi \setminus \{j\}} \varphi_k \otimes (u_jAu_j^{-1}\varphi_j).
\]

Symbolically: \( \pi_j(A) := I_1 \otimes I_2 \otimes \cdots \otimes I_{j-1} \otimes A \otimes I_{j+1} \otimes \cdots \), if \( \Pi = \mathbb{Z}_+ \setminus \{0\} \).

Unitary group action \( U_\Pi \) of \( G \) on \( \mathcal{H}_\Pi \) is determined by

\[
U_\Pi(g)\Phi := \bigotimes_{j \in \Pi} (u_jU(g)u_j^{-1}\varphi_j).
\]

For \( |\Pi| := \) the cardinality of \( \Pi \) finite, the representation \( U_\Pi \) is strongly continuous with generators

\[
X_\xi^\Pi := \sum_{j \in \Pi} \pi_j(X_\xi), \quad \xi \in \mathfrak{g}.
\]

\( U_\Pi \) is not weakly continuous in the case of infinite \( \Pi \) : If \( \varphi \in \mathcal{H} \) is not an eigenvector of \( X_\xi \), \( \varphi_j := u_j\varphi \) for all \( j \in \Pi \), \( ||\varphi|| = 1 \) and \( \Phi \) is the corresponding product-vector (5.1.11) in \( \mathcal{H}_\Pi \), then \( ||\Phi|| = 1 \) and

\[
(\Phi, U_\Pi(\exp(t\xi))\Phi) = 0
\]

for all sufficiently small \( |t| \neq 0, t \in \mathbb{R} \), since

\[
|\langle \varphi_j, u_j\exp(-itX_\xi)u_j^{-1}\varphi_j \rangle| = |\langle \varphi, \exp(-itX_\xi)\varphi \rangle| < 1 \quad \text{if} \quad e^{-itX_\xi}\varphi \neq \lambda\varphi,
\]

for any \( \lambda \in \mathbb{C} \), i.e. the function in (5.1.15) is discontinuous at \( t = 0 \).

5.1.4. Notes on the structure of CTPS.

We shall not give here a thorough definition of CTPS. We shall assume that the definitions of (convergence and quasiconvergence of) infinite products and sums of complex numbers as well as of the scalar product in \( \mathcal{H}_\Pi \) according to [227] are known to the reader. Let \( z \in \mathbb{C}^\Pi \) i.e. \( z \) is a function

\[
z : \Pi \to \mathbb{C}, \quad j \mapsto z_j.
\]

Assume that \( |z_j| = 1 \) for all \( j \in \Pi \) and define a unitary operator \( U_z \) on \( \mathcal{H}_\Pi \) by its linear action on product vectors (5.1.11) (the set of which is total in \( \mathcal{H}_\Pi \)) given by

\[
U_z\Phi := \bigotimes_{j \in \Pi} (z_j\varphi_j).
\]

Let \( \{\varphi^n : n \in \mathbb{Z}_+\} \) be an orthonormal basis in \( \mathcal{H} \). Let \( a, b \in \mathbb{Z}_+^\Pi \) with components \( a_j, b_j \in \mathbb{Z}_+ \) (\( j \in \Pi \)), and set
For $a \neq b$, the vectors $\Phi^a$ and $\Phi^b$ are mutually orthogonal: $(\Phi^a, \Phi^b) = 0$. Let $\Phi := \Phi^a$ for some $a$ (this can be done so for any normalized product-vector $\Phi \in \mathcal{H}_\Pi$ by a choice of the identifications $u_j$, $j \in \Pi$, of $\mathcal{H}_j$ with $\mathcal{H}$). The vectors $\Phi^b$, for which $b_j = a_j$ for all $j \in \Pi \setminus J_b$, $b_j \in \mathbb{Z}_+$ for all $j \in J_b$, where $J_b$ runs over all finite subsets of $\Pi$, form an orthonormal basis in a closed subspace of $\mathcal{H}_\Pi$ denoted by $\mathcal{H}_\Pi^b$ and called ITPS (incomplete tensor product space). Let $P_\Phi$ be the orthogonal projector in $\mathcal{H}_\Pi$ onto $\mathcal{H}_\Pi^\Phi$. For two arbitrary product vectors $\Phi, \Psi \in \mathcal{H}_\Pi$ the projectors $P_\Phi$ and $P_\Psi$ are either orthogonal or equal. For any $U_z$ from (5.1.18) we have

$$U_z P_\Phi U_z^* = P_{U_z \Psi},$$

(5.1.20)

and the product vectors $\Psi$ and $U_z \Psi$ are weakly equivalent. If $P_\Psi \Psi = \Psi$ (hence $P_\Psi \Phi = \Phi$), then $\Phi$ and $\Psi$ are (strongly) equivalent. The set of all product vectors $\Phi$ weakly equivalent to a product vector $\Psi$ form a total set in a closed subspace of $\mathcal{H}_\Pi$ with the orthogonal projector $P_{\Psi}$. Clearly, $P_{\Psi}$ is the sum of all such $P_\Phi$, which correspond to mutually strongly inequivalent product vectors $\Phi$, all of them being weakly equivalent to $\Psi$. The sum of all mutually strongly inequivalent $P_\Psi$ (we use an obvious licence in language) is the unit operator in $\mathcal{H}_\Pi$.  

Let $\mathfrak{A}_\Pi$ denotes the $C^*$-subalgebra of the algebra of all bounded operators on $\mathcal{H}_\Pi$ (denoted by $\mathcal{L}(\mathcal{H}_\Pi)$), generated by the elements

$$\{ \pi_j(A) \in \mathcal{L}(\mathcal{H}_\Pi) : A \in \mathcal{L}(\mathcal{H}), \ j \in \Pi \},$$

(5.1.21)

where $\mathcal{L}(\mathcal{H})$ is the algebra of all bounded operators on the Hilbert space $\mathcal{H}$. For any $x \in \mathfrak{A}_\Pi$, the following relations are valid, [227]:

$$[x, P_\Psi] = [x, U_z] = 0 \text{ for all } U_z, \text{ and for all } P_\Psi,$$

(5.1.22)

with $U_z$ from (5.1.18). If $p$ is another orthogonal projector in $\mathcal{L}(\mathcal{H}_\Pi)$, and for some product-vector $\Psi$ it is $pP_\Psi = p$, then

$$\text{if } [x, p] = 0 \text{ for all } x \in \mathfrak{A}_\Pi \Rightarrow p = P_\Psi \text{ or } p = 0,$$

(5.1.23)

i.e. irreducibility of the action of $\mathfrak{A}_\Pi$ in each $\mathcal{H}_\Pi^\Psi$. The weak closure of $\mathfrak{A}_\Pi$ in $\mathcal{L}(\mathcal{H}_\Pi)$ consists of all elements $x \in \mathcal{L}(\mathcal{H}_\Pi)$ satisfying (5.1.22). The action of $\mathfrak{A}_\Pi$ in $\mathcal{H}_\Pi^\Psi$ is a representation of this $C^*$-algebra. Such representations (all irreducible and faithful) for two product vectors are unitarily equivalent iff these vectors are weakly equivalent. The center of the weak closure of $\mathfrak{A}_\Pi$ in $\mathcal{L}(\mathcal{H}_\Pi)$ is generated by the projectors $P_{\Psi}$. Denote this weak closure by $\mathfrak{B}^\Psi$ and by $\mathfrak{Z}^\Psi$ its center: $x \in \mathfrak{Z}^\Psi \subset \mathfrak{B}^\Psi$ iff $[x, y] = 0$ for all $y \in \mathfrak{B}$.

1i.e. all the vectors $\Phi^b$ for which $b_j \neq a_j$ for finite number of indices $j \in \Pi$ only
2We shall use sometimes projectors instead of the corresponding subspaces.
5.1.5 Proposition. The mapping

$$\sigma : G \to {}^*\text{-Aut} \mathfrak{A}^\Pi, \ g \mapsto \sigma_g,$$

(5.1.24)

defined by (see (5.1.13))

$$\sigma_g(x) := U^\Pi(g)xU^\Pi(g^{-1}), \ \forall x \in \mathfrak{A}^\Pi, \ g \in G,$$

(5.1.25)

is a group homomorphism of $G$ into the group $^*\text{-Aut} \mathfrak{A}^\Pi$ of $^*$-automorphisms of the $C^*$-algebra $\mathfrak{A}^\Pi$. For any normalized vector $\Psi \in \mathcal{H}^\Pi$ define the vector state $\omega^\Psi$ on $\mathfrak{A}^\Pi$ by

$$\omega^\Psi : x \mapsto \omega^\Psi(x) := (\Psi, x\Psi).$$

(5.1.26)

The functions

$$g \mapsto \omega^\Psi(\sigma_g(x))$$

(5.1.27)

for any $x \in \mathfrak{A}^\Pi$ and any $\Psi \in \mathcal{H}^\Pi$ are continuous functions from $G$ to $\mathbb{C}$.

Proof. The mapping $A \mapsto U(g)AU(g^{-1})$ is a $^*$-automorphism of $\mathcal{L}(\mathcal{H})$, $A \in \mathcal{L}(\mathcal{H})$. Since $\mathfrak{A}^\Pi$ is generated by elements $x := \pi_j(A)$ ($j \in \Pi$, $A \in \mathcal{L}(\mathcal{H})$) defined in (5.1.12) (i.e. $\mathfrak{A}^\Pi$ is the norm-closure of finite linear combinations of finite products of such elements), the first statement follows from the definition (5.1.13) of $U^\Pi$. The functions (5.1.27) are continuous for all $x = \pi_j(A)$ and for all product states $\omega^\Psi$ (i.e. states corresponding via (5.1.26) to product vectors $\Psi$ of the form (5.1.11)). The set of product vectors is total in $\mathcal{H}^\Pi$ and any $^*$-automorphism of a $C^*$-algebra is norm-continuous. These facts imply by standard considerations validity of the last statement.

5.1.6 Note. Due to weak discontinuity of $U^\Pi$, the second statement of 5.1.5 is not valid if $\mathfrak{A}^\Pi$ would be replaced by its weak closure $\mathfrak{B}^\#$ in $\mathcal{L}(\mathcal{H}^\Pi)$. This can be seen by setting $\Psi := \Phi^a$ from (5.1.19) with $a_j := 0$ (for all $j \in \Pi$) and with a choice $\varphi^0 \in \mathcal{H}$ such that it is not an eigenvector of the generator $X_\xi$ of $U(G)$ for some $\xi \in \mathfrak{g}$. Then, setting $x := P^w_\Psi \in \mathfrak{B}^\#$ in (5.1.26), the function

$$t \mapsto \omega^\Psi(\sigma_{\exp(t\xi)}(P^w_\Psi))$$

(5.1.28)

is discontinuous at $t = 0$: For $t = 0$ its value equals to 1, but for arbitrarily small nonzero values of $t \in \mathbb{R}$ the values of (5.1.28) are found to be zero.

5.1.7. To simplify notations, we shall set $\Pi := \mathbb{Z}_+ \setminus \{0\}$ for the rest of the present section. For a densely defined linear operator $A$ on $\mathcal{H}$ with domain $D(A)$, let

$$D^\Pi(A) := \bigotimes_{j \in \Pi} u_jD(A)$$

(5.1.29)

be the linear subset of $\mathcal{H}^\Pi$ consisting of finite linear combinations of product vectors $\Phi$, (5.1.11), with $\varphi_j \in u_jD(A)$ ($j \in \Pi$). $D^\Pi(A)$ is not, in general, dense in $\mathcal{H}^\Pi$. Let
be (densely defined) operators on \( \mathcal{H}_\Pi \), a common domain of which contains \( D_\Pi(A) \). Let \( D_\Pi(A) \) be the set of vectors \( \Psi \in \mathcal{H}_\Pi \) such that

\[
A_\Pi \Psi := \text{norm} - \lim_{N \to \infty} A_N \Psi
\]  

exists in \( \mathcal{H}_\Pi \). The set \( D_\Pi(A) \) is a nonzero linear subset of \( \mathcal{H}_\Pi \): for \( \varphi \in D(A) \) and \( \varphi_j := u_j \varphi \) \((j \in \Pi)\), the product vector \( \Phi \) from (5.1.11) belongs to \( D_\Pi(A) \). Let \( \{\varphi^n : n \in \mathbb{Z}_+\} \subset D(A) \) be an orthonormal basis in \( \mathcal{H} \) and, for some \( a \in \mathbb{Z}_+^\Pi \), let \( \Phi^a \) defined according to (5.1.19) belongs to \( D_\Pi(A) \). Then, for \( b \in \mathbb{Z}_+^\Pi \) differing from \( a \) in at most finite number of components, it is \( \Phi^b \in D_\Pi(A) \). With \( \Psi := \Phi^a \), such vectors \( \Phi^b \) form an orthonormal basis in \( \mathcal{H}_\Pi^\Psi \), hence \( P_\Psi D_\Pi(A) \) is dense in \( \mathcal{H}_\Pi^\Psi \), and (5.1.31) give a densely defined operator on \( \mathcal{H}_\Pi^\Psi \). For any product vector \( \Psi \in D_\Pi(A) \), let us define a densely defined operator on \( \mathcal{H}_\Pi^\Psi \):

\[
A^\Psi := P_\Psi A_\Pi P_\Psi = P_\Psi A_\Pi.
\]  

The second equality is a consequence of the obvious commutativity of \( A_\Pi \) with \( P_\Psi \) for any product vector \( \Psi \in D_\Pi(A) \). The restriction of \( A_\Pi \) to the subspace \( \mathcal{H}_\Pi^\Psi \) (which clearly is a linear, not densely defined operator on \( \mathcal{H}_\Pi \)) will be denoted by \( A_\Pi^\Psi \), or simply \( A^\Psi \) \((\Psi \in D_\Pi(A))\). Now it is easy to prove

5.1.8 Lemma. For a densely defined operator \( A \) on \( \mathcal{H} \), let \( \Psi \in D_\Pi(A) \) be a product vector in \( \mathcal{H}_\Pi \). Then \( A^\Psi = \lambda P_\Psi \) for some \( \lambda \in \mathbb{C} \), on \( D_\Pi(A) \).

Proof. Since \( \Psi \in D_\Pi(A) \) is a product vector, it is also \( \Psi \in D_\Pi^\Psi \). We shall assume that \( \Psi \) is normalized. Then it can be written in the form

\[
\Psi = \bigotimes_{j=1}^N \varphi_j, \text{ with } u_j^{-1} \varphi_j \in D(A) \text{ for } j = 1, 2, \ldots,
\]  

where each \( \varphi_j \) \((j \in \Pi)\) is normalized in \( \mathcal{H}_j \): \( \|\varphi_j\|^2 = (\varphi_j, \varphi_j) = 1 \). Let \( \Psi_k \in D_\Pi^\Psi \) \((k = 1, 2)\) be such product vectors in \( \mathcal{H}_\Pi^\Psi \) which differ from (5.1.33) at most in the first \( n \) factors \( \varphi_j \). Such vectors \( \Psi_k \), with \( n \in \Pi \), form a total set in \( \mathcal{H}_\Pi^\Psi \). We have

\[
(\Psi_1, A^\Psi \Psi_2) = \lim_{N \to \infty} \frac{1}{N} \left( \sum_{j=1}^n (\Psi_1, \pi_j(A) \Psi_2) + \sum_{j=n+1}^N (\Psi_1, \pi_j(A) \Psi_2) \right) = \lim_{N \to \infty} \frac{1}{N} \sum_{j=n+1}^N (\varphi_j, u_j A u_j^{-1} \varphi_j) (\Psi_1, \Psi_2) = \lim_{N \to \infty} \frac{1}{N} \sum_{j=1}^N (\Psi, \pi_j(A) \Psi) (\Psi_1, \Psi_2) = (\Psi, A^\Psi \Psi) (\Psi_1, \Psi_2).
\]
5.1. MULTIPLE SYSTEMS

By linearity, the obtained relation extends to all \( \Psi_k \in P_\Psi D_\Pi(A) \). On that domain, we obtain

\[
A^\Psi = Tr(P_\Psi^o A^\Psi) P_\Psi = Tr(P_\Psi^o A_\Pi) P_\Psi,
\]

where \( P_\Psi \) is the projector onto the one-dimensional subspace of \( \mathcal{H}_\Pi^\Psi \) spanned by the vector \( \Psi \).

**Note:** Since \( A^\Psi \) is bounded on \( \mathcal{H}_\Pi \) (if \( \Psi \in D_\Pi(A) \) is a product-vector), we shall extend this operator to the whole \( \mathcal{H}_\Pi \) by continuity and we shall denote this extension by the same symbol, hence: \( A^\Psi \in \mathcal{L}(\mathcal{H}_\Pi) \).

**5.1.9 Proposition.** Let \( \Psi \in D_\Pi(g) \) be an arbitrary vector from

\[
D_\Pi(g) := \bigcap_{\xi \in g} D_\Pi(X_\xi),
\]

in the notation of 5.1.3 and 5.1.7. Then \( U_\Pi(g) \Psi \in D_\Pi(g) \), for all \( g \in G \). In particular, with \( g \cdot \Psi := U_\Pi(g) \Psi \), we have for product-vectors \( \Psi \in D_\Pi(g) \):

\[
X_\xi^\Psi = Tr(P_\Psi^o X_\xi \pi_\Psi) P_\Psi = Tr(P_\Psi^o X_{\text{Ad}(g^{-1})\xi} \pi_\Psi) P_\Psi.
\]

**Proof.** According to Lemma 3.1.4, \( U(g) X_\xi U(g^{-1}) = X_{\text{Ad}(g)\xi} \) for any \( \xi \in g \). Then, according to 5.1.3, we have also

\[
U_\Pi(g^{-1}) \pi_j(X_\xi) U_\Pi(g) = \pi_j(X_{\text{Ad}(g^{-1})\xi}).
\]

For \( \Psi \in D_\Pi(g) \) there exists \( X_\xi^\Psi \) for all \( \xi \in g \). Because of continuity of unitary operators \( U_\Pi(g) \) for any fixed \( g \in G \), there exist also the limits

\[
\lim_{N \to \infty} U_\Pi(g) X_{\text{Ad}(g^{-1})\xi N} \Psi = U_\Pi(g) X_{\text{Ad}(g^{-1})\xi} \Psi
\]

for all \( \xi \in g \). Rewriting the expression on the left hand side of (5.1.39) we get

\[
U_\Pi(g) X_{\text{Ad}(g^{-1})\xi N} \Psi = \frac{1}{N} \sum_{j=1}^N U_\Pi(g) \pi_j(X_{\text{Ad}(g^{-1})\xi}) \Psi = X_{\xi N} U_\Pi(g) \Psi.
\]

This shows that the limit of the right hand side of (5.1.40) for large \( N \) exists for any \( \xi \in g \), what proves the first assertion. The proof of the second assertion is a corollary of the proof of the first one for the case of a product vector \( \Psi \in D_\Pi(g) \), obtained from (5.1.35).

**5.1.10.** For a product vector \( \Psi \in D_\Pi(g) \), let \( \omega^\Psi \) be the corresponding state on \( \mathfrak{g}^\Pi \) defined in (5.1.26). We shall denote the obvious extension of this state to the unbounded observables \( X_{\xi N} \) (\( N \in \Pi \)) by the same symbol. Then we have

\[
\lim_{N \to \infty} \omega^\Psi(X_{\xi N}) = Tr(P_\Psi^o X_{\xi \Pi}) =: \omega_\Psi(X_{\xi \Pi}).
\]
We see that the value of expressions in (5.1.41) can be interpreted as the value of the intensive (unbounded) observable $X_{\xi\Pi}$ in the state $\omega^\Psi$. Define the linear functional $F_\Psi \in g^*$ by

$$F_\Psi : \xi \mapsto F_\Psi(\xi) := \text{Tr}(P_\Psi^\rho X_{\xi\Pi}), \text{ for product vectors } \Psi \in D_\Pi(g).$$  \hfill (5.1.42)

According to (5.1.37), the action $g \cdot F_\Psi := F_{g\cdot\Psi}$ of $G$ coincides with the $Ad^*(G)$-action:

$$(g \cdot F_\Psi)(\xi) = F_{g\cdot\Psi}(\xi) = F_\Psi(Ad(g^{-1})\xi) = (Ad^*(g)F_\Psi)(\xi).$$ \hfill (5.1.43)

According to 5.1.9, the set of product vectors in $D_\Pi^{\Psi}(g)$ is $U^{\Pi(G)}$-invariant, hence any point of the orbit $G \cdot F_\Psi$ has the form (5.1.42).

Define the group homomorphism $\sigma^*$ of $G$ into the group of affine transformations of the state-space $S(\mathfrak{A}^{\Pi})$:

$$\sigma^* : G \to \sigma^*_G, \ g \mapsto \sigma^*_g, \text{ where } (\sigma^*_g \omega)(x) := \omega(\sigma_g^{-1}(x))$$ \hfill (5.1.44)

for all $g \in G, \ \omega \in S(\mathfrak{A}^{\Pi})$ and $x \in \mathfrak{A}^{\Pi}$ with $\sigma_g$ defined in (5.1.25). Let $\Psi \in D_\Pi(g)$ be a product vector and

$$O_\Psi := \{\sigma^*_g \omega^\Psi : g \in G\} \subset S(\mathfrak{A}^{\Pi})$$ \hfill (5.1.45)

be the orbit through $\omega^\Psi$ of the action $\sigma^*_G$. For $\omega \in O_\Psi$ let

$$F_\omega \in g^* : F_\omega(\xi) := \omega(X_{\xi\Pi}).$$ \hfill (5.1.46)

Let us write also $g \cdot \omega := \sigma^*_g \omega$. Clearly $g \cdot \omega^\Psi := \omega^\Psi$. According to (5.1.43), the mapping $F$ from the state space into the dual $g^*$ of the Lie algebra:

$$F : O_\Psi \to g^*, \ \omega \mapsto F(\omega) := F_\omega,$$ \hfill (5.1.47)

maps the orbit $O_\Psi$ onto an orbit of $Ad^*(G)$. Let

$$[\omega] := F^{-1}(F_\omega), \text{ for } \omega \in O_\Psi, \text{ be equivalence classes in } O_\Psi.$$  

The corresponding factor space $M_\Psi$ is mapped by $F$ (which is constant on classes $[\omega]$) bijectively onto the orbit $G \cdot F_\Psi$. The last orbit is endowed by the Kirillov-Kostant symplectic structure. The functions $f_\xi$ on $M_\Psi$:

$$[\omega] \mapsto f_\xi(\omega) := \omega(X_{\xi\Pi}), \ \omega \in O_\Psi, \ \xi \in g,$$ \hfill (5.1.48)

are the Hamiltonian functions generating the flows

$$(t; [\omega]) \mapsto [\exp(t\xi) \cdot \omega].$$ \hfill (5.1.49)

Corresponding Poisson brackets are:

$$\{f_\xi, f_\eta\}(\omega) = -F_\omega([\xi, \eta]), \ \xi, \eta \in g,$$ \hfill (5.1.50)
5.1. MULTIPLE SYSTEMS

compare e.g. (3.2.2). Here it is assumed that \(M_\Psi\) is endowed by the manifold structure of the \(Ad^*(G)\)-orbit \(F(M_\Psi)\). We have obtained here classical phase spaces from equivalence classes of states in \(S(\mathfrak{A}^\Pi)\) determined by the group action \(\sigma_G^\ast\). Although the construction is formally parallel to that in the case of finite systems, there are certain physically significant differences in the interpretation, as mentioned in 1.1.6.

5.1.11. Let \(P_G\) be the orthogonal projector in \(L(\mathcal{H}_\Pi)\) onto the subspace of \(\mathcal{H}_\Pi\) spanned by all product vectors \(\Psi \in D_\Pi(\mathfrak{g})\). The operator \(P_G\) is equal to the sum of all mutually orthogonal projectors \(P_w\) corresponding to the product vectors \(\Psi \in D_\Pi(\mathfrak{g})\), as is seen from (5.1.35) and obvious commutativity of any \(A_\Pi\) with all the \(U_z\), (5.1.18). Hence

\[P_G \in \mathfrak{Z} := \text{the center of } (\mathfrak{A}^\Pi)^{**}\]

be the support of \(\rho\), i.e. \((I-s_G)(\mathfrak{A}^\Pi)^{**}\) is the kernel of \(\rho\) (I is here the identity of \((\mathfrak{A}^\Pi)^{**}\)). The restriction \(\rho_G\) to \(s_G(\mathfrak{A}^\Pi)^{**}\) of \(\rho\) is an isomorphism of \(W^*\)-algebras (which is \(\sigma - \sigma\) continuous, see [274, 1.21.13+4.1.23]). Let \(S_\mathfrak{g} \subset S(\mathfrak{A}^\Pi)\) consists of such states \(\omega\) , the central supports \(s_\omega \in \mathfrak{Z}\) of which are contained in \(s_G\), i.e. \(s_\omega s_G = s_\omega\) (the central support of a state is defined as the central support, equiv. central cover - cf. [235, 3.8.1],[306],[274, 1.14.2], of the extension to \((\mathfrak{A}^\Pi)^{**}\) of the corresponding cyclic representation of \(\mathfrak{A}^\Pi\)). The set \(S_\mathfrak{g}\) will play an important role in the following.

The automorphisms \(\sigma_\mathfrak{g}\) \((\mathfrak{g} \in G)\), (5.1.25), have unique extensions to automorphisms of the \(W^*\)-algebra \((\mathfrak{A}^\Pi)^{**}\), which are \(\sigma - \sigma\) and also norm - norm continuous, [274, 1.21.13]. The \(\sigma_\mathfrak{g}\) can be understood also as an (uniquely defined) automorphism of the von Neumann algebra \(\mathfrak{B}^\#\). Due to Proposition 5.1.9, it is

\[\sigma_\mathfrak{g}(P_G) = P_G \text{ for all } \mathfrak{g} \in G,\]

hence also

\[\sigma_\mathfrak{g}(s_G) = s_G, \quad \mathfrak{g} \in G.\]

Let us keep the notation \(X_\mathfrak{g}\Pi\) \((\xi \in \mathfrak{g})\) for the closures of the restrictions to \(P_G \mathcal{H}_\Pi\) of operators denoted previously by the same symbols. According to (5.1.37), all the \(X_\xi\Pi\)'s have
in \( P_G \mathcal{H}_\Pi \) a common complete orthonormal set (a basis) of eigenvectors consisting of product vectors \( \Psi \in D_\Pi(G) \), with real eigenvalues. Hence, they form a set of mutually commuting selfadjoint operators on \( P_G \mathcal{H}_\Pi \). Let \( E_{\xi \Pi}^H(B) \) \((B := \text{any Borel subset of } \mathbb{R})\) be projectors forming their spectral measures \( E_{\xi \Pi}^H \). All these projectors belong to \( P_G \mathfrak{F}^# \), since any \( X_{\xi \Pi} (\xi \in \mathfrak{g}) \) is a constant on each \( P^w_\Psi < P_G \). Define

\[
E_{\xi \Pi}(B) := \rho_G^{-1}[E_{\xi \Pi}^H(B)] \in s_G \mathfrak{F} \quad \text{for all } \xi \in \mathfrak{g} \text{ and Borel } B \subset \mathbb{R}. \tag{5.1.54}
\]

Any \( E_{\xi \Pi} (\xi \in \mathfrak{g}) \) is a resolution of identity in the \( W^\ast \)-algebra \( s_G \mathfrak{F} \). Let us define also

\[
E_{\xi \Pi}'(B) := E_{\xi \Pi}(B), \text{ if } B \text{ does not contain the zero } 0 \in \mathbb{R}, \tag{5.1.55}
\]

\[
:= E_{\xi \Pi}(B) + I - s_G, \text{ if } 0 \in B.
\]

Here \( I \) is the identity of \( \mathfrak{F} \). Then \( E_{\xi \Pi}' (\xi \in \mathfrak{g}) \) is a resolution of identity in \( \mathfrak{F} \).

5.1.12 Definition. Let \( \mathfrak{M}_G \) be the \( W^\ast \)-subalgebra of \( \mathfrak{F} \) generated by projectors \( E_{\xi \Pi}(B) \) \((\xi \in \mathfrak{g}, B - \text{Borel in } \mathbb{R})\) and by \( I \). \( \mathfrak{M}_G \) is called the algebra of \( G \)-macroscopic observables of the system \((\mathfrak{A}^\Pi, \sigma_G)\), or simply the \((G-)\)-macroscopic algebra. Let \( \mathfrak{N}_G := s_G \mathfrak{M}_G \) be the \( W^\ast \)-subalgebra of \( \mathfrak{M}_G \) generated by projectors \( E_{\xi \Pi}(B) \) and called the algebra of \( G \)-definiteness of \((\mathfrak{A}^\Pi, \sigma_G)\), or sometimes also the \((G-)\)-macroscopic algebra, if there will be no confusion possible.

5.1.13 Lemma. Let \( \xi_j \) \((j = l, 2, \ldots n := \dim G)\) form a basis in \( \mathfrak{g} \). For \( \lambda \in \mathbb{R}^n \) let \( F := \sum_j \lambda_j F_j \in \mathfrak{g}^* \) expressed in the corresponding dual basis \( \{F_j\} \subset \mathfrak{g}^* \). Let

\[
E_\varphi(F) := E_{\xi_{\Pi}}(\lambda_1) E_{\xi_{\Pi}}(\lambda_2) \ldots E_{\xi_{\Pi}}(\lambda_n) \in \mathfrak{N}_G. \tag{5.1.56}
\]

The projectors \( E_\varphi(F) \) \((F \in \mathfrak{g}^*)\) do not depend on a specific choice of the basis in \( \mathfrak{g} \) and they are all minimal projectors in \( \mathfrak{N}_G \).

Proof. The restriction of the mapping \( \rho_G \) to \( \mathfrak{N}_G \) is a \( W^\ast \)-isomorphism of \( \mathfrak{N}_G \) into \( P_G \mathfrak{B}^# \subset \mathfrak{B}^# \). Let \( \Psi \in \rho_G(E_\varphi(F)) \mathcal{H}_\Pi \). From linearity of the mapping \( \xi \mapsto X_{\xi \Pi} \) for \( \xi = \sum_j \tau_j \xi_j \), we have

\[
X_{\xi \Pi} \Psi = \sum_j \tau_j X_{\xi_j \Pi} \Psi = \sum_j \tau_j \lambda_j \Psi = F(\xi) \Psi. \tag{5.1.57}
\]

The second equality is due to the definition of \( E_{\xi \Pi}(\lambda_j) \) as the projector corresponding to the eigenvalue \( \lambda_j \in \mathbb{R} \) of \( X_{\xi \Pi} \) (we write \( \lambda_j \) in the place of the one-point set \( \{\lambda_j\} \) for simplicity). The last equality in (5.1.57) is due to definition of the dual basis and shows the stated independence of \( E_\varphi(F) \) on the choice of a basis.

Let

\[
E_\varphi^#(F) := \rho_G(E_\varphi(F)).
\]

Any projector \( E_\varphi^#(B) \) is a sum (uncountable - in general, see also [274, 1.13.4]) of projectors \( E_\varphi^#(F) \) \((F(\xi) \in B)\). The algebra \( \rho_G(\mathfrak{N}_G) \) is the double commutant of the set.
\[ \{ E^\#_0(F) : F \in \mathfrak{g}^* \}, \tag{5.1.58} \]

according to the bicommutant theorem by von Neumann taken in the algebra \( \mathcal{L}(P_G \mathcal{H}_\Pi) \) of bounded operators on \( P_G \mathcal{H}_\Pi \). All the projectors \( E^\#_0(F) \) in (5.1.58) are mutually orthogonal. The commutant of (5.1.58) contains all the orthogonal projectors \( p \leq E^\#_0(F) \). But any nonzero orthogonal projector \( q < E^\#_0(F) \) (strict inequality!) cannot commute with all such \( p \)’s. Hence \( E^\#_0(F) \) is minimal in \( \rho_G(\mathfrak{N}_G) \) and \( E_G(F) \) is minimal in \( \mathfrak{N}_G \) for any \( F \in \mathfrak{g}^* \). Since \( E_{\Pi}(\mathbb{R}) = s_G \) (= the identity of \( \mathfrak{N}_G \)) is a sum of \( E^\#_0(F) \)’s and \( \mathfrak{N}_G \) is commutative, the set of all the \( E^\#_0(F) \)’s exhausts the set of all the minimal projectors in \( \mathfrak{N}_G \).

\[ \square \]

5.1.14. Any state \( \omega \in \mathcal{S}(\mathfrak{A}^\Pi) \) on the algebra of bounded observables of our system has unique extension to a normal state on the algebra \( (\mathfrak{A}^\Pi)^{**} \) and its restriction to \( \mathfrak{M}_G \) is a normal state \( \omega \in \mathcal{S}(\mathfrak{M}_G) \). Any normal state on \( \mathfrak{M}_G \) can be obtained in this way, [274, 1.24.5]. Let \( \mathcal{M} \) be the **spectrum space** of \( \mathfrak{M}_G \), i.e. the compact set of all pure states on \( \mathfrak{M}_G \) endowed with the induced topology from the \( w^* \)-topology of its dual \( \mathfrak{M}_G^* \). Then \( \mathfrak{M}_G \) is isomorphic (denoted by \( \sim \)) to the \( C^* \)-algebra \( C(\mathcal{M}) \) of all complex valued continuous functions on \( \mathcal{M} \) (by a Gel’fand-Najmark theorem, cf. [223, 16.2 Thm.1],[53, Thm.2.1.11A]): \( x (\in \mathfrak{M}_G) \leftrightarrow \hat{x} (\in C(\mathcal{M})) \).

An element \( x \in \mathfrak{M}_G \) is an orthogonal projector iff the corresponding element \( \hat{x} \in C(\mathcal{M}) \) is characteristic function of some Borel subset \( B \) of \( \mathcal{M} \), i.e.

\[ \hat{x}(m) = \chi_B(m) \text{ for all } m \in \mathcal{M}. \]

A pure state \( m \in \mathcal{M} \) is normal, iff the characteristic function \( \chi_{\{m\}} \) of the one-point set \( \{m\} \) is continuous, \( \chi_{\{m\}} \in C(\mathcal{M}) \). This means, that **normal pure states** on \( \mathfrak{M}_G \) are just the isolated points of \( \mathcal{M} \). The corresponding projectors \( \chi_{\{m\}} \) are **minimal projectors** in \( \mathfrak{M}_G \sim C(\mathcal{M}) \). The spectrum space \( \mathcal{M} \) is Hausdorff and the family of **clopen** (i.e. closed and open) **sets** forms a basis of the topology of \( \mathcal{M} \), cf. [274]. Hence, any minimal projector in \( C(\mathcal{M}) \) is of the form \( \chi_{\{m\}} \).

Any state \( \omega \in \mathcal{S}(\mathfrak{M}_G) \) is represented by a probability Baire (i.e. regular Borel) measure on \( \mathcal{M} \) and any such measure \( \mu_\omega \) represents a state on \( \mathfrak{M}_G : \omega(x) = \mu_\omega(\hat{x}) \), where \( x \) in the left hand side is an element of the abstract algebra \( \mathfrak{M}_G \) and \( \hat{x} \) in the right hand side denotes the corresponding function \( \hat{x} \in C(\mathcal{M}) \). Any pure state \( m \in \mathcal{M} \) corresponds to the Dirac measure \( \delta_m \).

5.1.15. The algebra \( \mathfrak{M}_G \) (and also \( \mathfrak{N}_G \)) is \( \sigma_G \)-invariant:

\[ \sigma_g x \in \mathfrak{N}_G \text{ for all } g \in G \text{ and any } x \in \mathfrak{N}_G. \tag{5.1.59} \]

This is a consequence of the relation (compare the proof of 5.1.9)

\[ U_\Pi(g) X_{\xi \Pi} U_\Pi(g^{-1}) = X_{\text{Ad}(g)\xi \Pi}, \quad (g \in G, \; \xi \in \mathfrak{g}), \tag{5.1.60} \]

what implies

\[ \sigma_g [E_{g}(B)] = E_{\text{Ad}(g)\xi}(B) \quad (g \in G \text{ and Borel } B \subset \mathbb{R}), \tag{5.1.61} \]
due to uniqueness of spectral measures of selfadjoint operators and also due to continuity properties of the used mappings. From (5.1.61), we obtain immediately (by calculation of the eigenvalues of $X_{\xi \Pi}$):

$$\sigma_g[E_g(F)] = E_g(Ad^*(g)F), \quad (g \in G, \ F \in g^*) \quad (5.1.62)$$

This specifies, according to 5.1.13 and 5.1.14, the action of $G$ on the set of all normal pure states on $\mathcal{M}_G$. The remaining normal pure state on $\mathcal{M}_G$ corresponds to the $\sigma_G$-invariant minimal projector $I - s_G$. Hence, $\sigma_G$ acts on $\mathcal{M}_G$ as a group of $W^*$-automorphisms and $\sigma_G^*$ acts on $\mathcal{M}$ (resp. on $S(\mathcal{M}_G)$) as a group of homeomorphisms (resp. a group of continuous affine transformations). As a consequence, the orbits

$$O_\omega := \{\sigma_g^* \omega : \ g \in G\} \subset S(\mathcal{M}_G) \quad (5.1.63)$$

are canonically mapped onto orbits of $\sigma_G^*$ in $S(\mathcal{M}_G)$ consisting of normal states on $\mathcal{M}_G$. By this mapping orbits consisting of vector states $\omega_\Psi$ are mapped onto orbits in $\mathcal{M}$. The functions

$$\sigma^*_m : \ G \to \mathcal{M}, \ g \mapsto \sigma^*_m(g) := \sigma_g^*m, \ (m \in \mathcal{M}) \quad (5.1.64)$$

are not continuous in the given topology on $\mathcal{M}$, 5.1.14. The orbits of $\sigma_G^*$ consisting of normal pure states on $\mathcal{M}_G$ are, due to (5.1.62), bijective images of (some) orbits of $Ad^*(G)$ in $G^*$. It is also clear that the normal pure states on $\mathcal{M}_G$ form a $G$-invariant subset $\mathcal{M}_*$ of all states $S(\mathcal{M}_G)$ on $\mathcal{M}_G$:

$$\sigma_G^* \mathcal{M}_* = \mathcal{M}_*, \ i.e. \ m \in \mathcal{M}_* \Rightarrow \sigma_g^*m \in \mathcal{M}_* \ for \ all \ g \in G \ (\sigma_g^*m \equiv m). \quad (5.1.65)$$

5.1.16 Proposition. Let $p = p^* = p^2 \in \mathcal{M}_G$ be any projector and

$$pg^* := \{F \in g^* : 0 \neq E_g(F) \leq p\}. \quad (5.1.66)$$

Let $J \subset g^*$ be a finite set and let by $p_J$ be denoted

$$p_J := \sum_{F \in J} E_g(F), \ for\ any\ finite\ J \subset g^*. \quad (5.1.67)$$

Denote further for any subset $K \subset g^*$:

$$c(K) := \text{l.u.b.}\{p_J : J \subset K, \ J \text{ finite}\}. \quad (5.1.68)$$

Assume $ps_G = p$.

Then the following assertions are fulfilled:

(i) $p = c(pg^*)$, and (ii) $\mathcal{M} = \overline{\mathcal{M}_*} := \text{the closure of } \mathcal{M}_*$.  

3Where $\Psi \in \mathcal{H}_\Pi$ such that there is an $F \in g^*$ satisfying: $E^*_g(F)\Psi = \Psi$. 

Proof. The projector \( s_G \) is constructed in such a way that \( \rho_G(s_G) = P_G \) and \( P_G = E_{\xi \Pi}^\#(\mathbb{R}) \) for any \( \xi \in \mathfrak{g} \). Since \( \rho_G \) is an isomorphism of \( \mathfrak{N}_G = s_G \mathfrak{M}_G \) into \( \mathfrak{F}^\# \), 5.1.11, it is \( s_G = c(s_G \mathfrak{g}^*) \). Hence, for any projector \( q = q_{sG} \) in \( \mathfrak{M}_G \), there is a nonzero minimal projector \( E_g(F_o) = E_g(F_o)q \), if \( q \) is nonzero. Let \( q := p - c(p \mathfrak{g}^*) \) \((\geq 0\), according to the definition (5.1.68)) and assume that \( q \neq 0 \). Let \( 0 \neq E_g(F_o) = qE_g(F_o) \). But \( E_g(F_o) \leq p \), hence \( E_g(F_o)c(p \mathfrak{g}^*) = E_g(F_o) \). This ia a contradiction, since \( q \) is orthogonal to \( c(p \mathfrak{g}^*) \). Hence \( q = 0 \), what proves (i).

Any projector in \( \mathfrak{M}_G \) is represented in \( C(\mathcal{M}) \) by the characteristic function of a clopen set, and conversely, the characteristic function of a clopen set in \( \mathcal{M} \) represents by Gel’fand isomorphism a projector in \( \mathfrak{M}_G \), 5.1.14. The minimal projector \( E_g(F) \) corresponds to the one-point clopen set \( \{m_F\} \) containing \( m_F \in \mathcal{M}_* \). The union of all \( \{m_F\} \) \((F \in \mathfrak{g}^*) \) is an open subset the closure of which is clopen, since \( \mathcal{M} \) is a Stonean space, see 5.1.14, and [274]. According to (i), it is the support of characteristic function corresponding to \( s_G = c(s_G \mathfrak{g}^*) = c(\mathfrak{g}^*) \). The projector \( s_G \) is the unit element in \( \mathfrak{N}_G \) and the projector \( I - s_G \) is minimal. This shows that the sum of the characteristic functions corresponding to \( s_G \) and \( I - s_G \) is the characteristic function of the whole \( \mathcal{M} \), i.e. \( \mathcal{M} \) is the union of a one-point set \( \{m_o\} \) corresponding to \( I - s_G \) and of the closure of \( \mathcal{N}_* := \mathcal{M}_* \setminus \{m_o\} = \{m_F : F \in \mathfrak{g}^*\} \), \(5.1.69\)

where we set \( \{m_F\} := \emptyset := \) the empty set, if \( E_g(F) = 0 \). This is (ii).

\[ \square \]

**Notation:** Let us introduce, for following usage, some further concepts. Let

\[ \mu_\omega^\xi : B \to \mu_\xi^\omega(B) := \omega(E_{\xi \Pi}(B)) \text{ for any } \omega \in S(\mathfrak{M}_G) \text{ and Borel } B \subset \mathbb{R} \text{, }5.1.70 \]

be a finitely additive Borel measure on \( \mathbb{R} \). For mutually dual bases \( \{\xi_j : j = 1,2,\ldots,n\} \) in \( \mathfrak{g} \) and \( \{F_j : j = 1,2,\ldots,n\} \) in \( \mathfrak{g}^* \) define \( \mu_\omega^\xi \) on \( \mathfrak{g}^* \) by:

\[ \mu_\omega^\xi(B) := \omega(E_{\xi_1 \Pi}(B_1)E_{\xi_2 \Pi}(B_2)\ldots E_{\xi_n \Pi}(B_n)) \text{ for } B := \{F \in \mathfrak{g}^* : F(\xi_j) \in B_j\} \text{. }5.1.71 \]

If \( \xi \in L^1(\mu_\omega^\xi,\mathfrak{g}^*) \) with \( \xi \in (\mathfrak{g}^*)^* = \mathfrak{g} \), then

\[ \omega(X_{\xi \Pi}) := \mu_\omega^\xi(\xi) = \int \lambda \mu_\omega^\xi(d\lambda) \text{. }5.1.72 \]

\[ 5.1.17 \text{ Lemma. The image by the natural map defined in 5.1.14 of any factor state } \omega \in S(\mathfrak{A}^{\Pi}) \text{ into } S(\mathfrak{M}_G) \text{ is an equally denoted pure state } \omega \in \mathcal{M}_* := \text{ the set of all normal pure states on } \mathfrak{M}_G. \]

**Proof.** The canonical cyclic representation \( \{\pi_\omega, \mathcal{H}_\omega, \varphi_\omega\} \) of \( \mathfrak{A}^{\Pi} \) (here \( \varphi_\omega \) is the cyclic vector in the Hilbert space \( \mathcal{H}_\omega \) for the representation \( \pi_\omega \)) such, that

\[ \omega(x) = (\varphi_\omega, \pi_\omega(x)\varphi_\omega) \text{. }5.1.73 \]

for all \( x \in \mathfrak{A}^{\Pi} \) corresponding to a factor state \( \omega \in S(\mathfrak{A}^{\Pi}) \) has trivial center. Hence, any projector in the center of the commutant \( \pi_\omega(\mathfrak{A}^{\Pi})' \) is trivial. The canonical extension to \( (\mathfrak{A}^{\Pi})'' \)
(i.e. unique \( W^* \)-continuous) of \( \pi_\omega \) maps the bidual \((\mathcal{A}_G)^\prime\) onto the double commutant \( \pi_\omega(\mathcal{A}_G)^{\prime\prime} \) by which \( \mathcal{M}_G \subset \mathcal{A}_G \) is mapped into the center \( \pi_\omega(\mathcal{A}_G) \) of this bicommutant. Since \( \pi_\omega(\mathcal{A}_G) \subset \pi_\omega(\mathcal{A}_G)^\prime \), any projector in \( \pi_\omega(\mathcal{M}_G) \) is trivial. The corresponding \( \omega \in \mathcal{S}(\mathcal{M}_G) \) is expressed by \((5.1.73)\) for \( x \in \mathcal{M}_G \). This \( \omega \) is normal: \( \omega \in \mathcal{S}_G(\mathcal{M}_G) \), hence there exists a unique projector \( s_\omega \) in (the center of) \( \mathcal{M}_G \) such that

\[
\omega(x) = \omega(xs_\omega) \forall \{ x \in \mathcal{M}_G : \omega(x^*x) = 0 \} \Rightarrow x = x(I - s_\omega).
\]  

(5.1.74)

Hence for any nonzero projector \( s \leq s_\omega \) one has \( \omega(s) \neq 0 \) and \( \pi_\omega(s) = I_\omega := \text{the identity of } \mathcal{L}(\mathcal{H}_\omega) \). From this follows \( \omega(s_\omega - s) = 0 \) and \( s_\omega - s = (s_\omega - s)(I - s_\omega) = 0 \), so that \( s_\omega \) is a minimal projector in \( \mathcal{M}_G \). This proves that \( \omega \in \mathcal{M}_* \).

**5.1.18.** For any state \( \omega \in \mathcal{S}_G \), the measures \( \mu_\xi^\omega \) (\( \xi \in g \)) are probability (\( \sigma \)-additive) regular Borel measures on \( \mathbb{R} \), due to normality of \( \omega \in \mathcal{S}(\mathcal{M}_G) \), \((5.1.70)\). Define the subset \( \mathcal{S}_G^d \subset \mathcal{S}(\mathcal{A}_G) \):

\[
\mathcal{S}_G^d := \{ \omega \in \mathcal{S}_G : \omega(X_{\xi^\Pi}) \text{ is finite for all } \xi \in g \},
\]

(5.1.75)

where \( \omega(X_{\xi^\Pi}) \) is defined in \((5.1.72)\). Due to \((5.1.61)\), the set \( \mathcal{S}_G^d \) is \( \sigma_G^* \)-invariant. For any \( f \in L^1(\mathbb{R}, \mu_\xi^\omega) \) define

\[
\omega(f(X_{\xi^\Pi})) := \int_{\mathbb{R}} f(\lambda)\omega(E_{\xi^\Pi}(d\lambda)).
\]

(5.1.76)

Any state \( \omega \in \mathcal{S}_G \) which is mapped into \( \mathcal{M}_* \), e.g. any pure state \( \omega \in \mathcal{S}_G \), belongs to \( \mathcal{S}_G^d \) and, moreover,

\[
\omega(X_{\xi^\Pi}^2) = [\omega(X_{\xi^\Pi})]^2 \text{ for all } \xi \in g.
\]

(5.1.77)

Denote \( F_\omega(\xi) := \omega(X_{\xi^\Pi}) \) for \( \omega \in \mathcal{S}_G^d \). The mapping

\[
F : \mathcal{S}_G^d \rightarrow g^*, \; \omega \mapsto F(\omega) := F_\omega; \; F_\omega(\xi) := \omega(X_{\xi^\Pi}), \; \xi \in g,
\]

(5.1.78)

maps orbits of \( \sigma_G^* \) in \( \mathcal{S}_G^d \) onto orbits of \( Ad^*(G) \) in \( g^* \). Let \( \omega \in \mathcal{S}_G^d \) and \( O_\omega := \sigma_G^*\omega \) be the corresponding orbit. If \((5.1.77)\) is valid for \( \omega \) then it is valid for all the states in \( O_\omega \), as it is seen from \((5.1.61)\). We shall call orbits \( O_\omega \subset \mathcal{S}_G^d \) satisfying \((5.1.77)\) the **G-macroscopically pure orbits**, and similarly for single states; simply, we shall use also \( (G\text{-})\text{pure orbits} \) (resp. **G-pure states**). The set of all G-pure states will be denoted by \( \mathcal{E}_G \) (\( \subset \mathcal{S}_G^d \)).

The state \( \omega \in \mathcal{E}_G \) need not be a (pure) state in \( \mathcal{E}(\mathcal{A}_G) \) or in \( \mathcal{E}\mathcal{S}_G \). But the following assertion is valid:

**5.1.19 Proposition.** For \( \omega \in \mathcal{S}_G^d \) and its canonical image \( \omega \in \mathcal{S}(\mathcal{M}_G) \) the following statements are equivalent:

(i) \( \omega \in \mathcal{E}_G \);  (ii) \( \omega \in \mathcal{M}_* \).
5.1. MULTIPLE SYSTEMS

Proof. The implication (ii) $\Rightarrow$ (i) is clear. Let $\omega \in \mathcal{E}_g$ and let $\mu_\omega$ be the Baire measure on $\mathcal{M}$ corresponding to $\omega \in S_*(\mathfrak{M}_G)$. We shall prove that $\mu_\omega$ is concentrated on a one point set $\{\omega\} \subset \mathcal{M}_s$. Let $B_n \subset \mathbb{R}$, $n \in \mathbb{Z}_+$, be an increasing absorbing sequence of Borel sets, i.e. for any bounded Borel $B \subset \mathbb{R}$ there is some $n_B \in \mathbb{Z}_+$ that for all $n \geq n_B$ it is $B \subset B_n$, and $B_n \subset B_{n+1}$ for $n \in \mathbb{Z}_+$. If $f : \mathbb{R} \to \mathbb{C}$ is any Borel function which is uniformly bounded on each bounded Borel subset $B$ of $\mathbb{R}$, then

$$E_{\xi\Pi}(B)f(X_{\xi\Pi}) := \int_B f(\lambda)E_{\xi\Pi}(d\lambda) = f(E_{\xi\Pi}(B)X_{\xi\Pi})$$  \hspace{1cm} (5.1.79)$$

is a well defined element of $\mathfrak{N}_G$, [274, 1.11.3]. Since $\omega$ is normal, we can write for such ‘locally finite’ functions $f \in L^1(\mathbb{R}, \mu_\omega)$:

$$\omega(f(X_{\xi\Pi})) = \lim_{n \to \infty} \omega(E_{\xi\Pi}(B_n)f(X_{\xi\Pi})), \quad (5.1.80)$$

$$\omega(E_{\xi\Pi}(B)f(X_{\xi\Pi})) = \int_{\mathcal{M}} m(E_{\xi\Pi}(B)f(X_{\xi\Pi}))\mu_\omega(dm), \quad (5.1.81)$$

$$m(E_{\xi\Pi}(B)f(X_{\xi\Pi})) = m(E_{\xi\Pi}(B))m(E_{\xi\Pi}(B)f(X_{\xi\Pi})); \quad (5.1.82)$$

in (5.1.82) we have used the character-property of $m \in \mathcal{M} := \mathfrak{E}\mathfrak{S}(\mathfrak{M}_G)$.

For $n \in \mathbb{Z}_+$, the function $\chi_{\xi n} : m \mapsto m(E_{\xi\Pi}(B_n))$ is continuous characteristic function of a clopen set $\mathcal{M}_{\xi n} \subset \mathcal{M}$. From the monotonicity property of spectral measures, we have $\mathcal{M}_{\xi(n+1)} \supset \mathcal{M}_{\xi n}$. The union

$$\bigcup_{n \in \mathbb{Z}_+} \mathcal{M}_{\xi n} =: \mathcal{M}_{\xi}$$  \hspace{1cm} (5.1.83)$$

is open, hence measurable together with all the $\mathcal{M}_{\xi n}$. We see from (5.1.80), (5.1.81) and (5.1.82) that $\mu_\omega$ is concentrated on $\mathcal{M}_{\xi}$:

$$\mu_\omega(\mathcal{M}_{\xi}) = \mu_\omega(\mathcal{M}) = 1, \quad \forall \xi \in \mathfrak{g}; \quad (5.1.84)$$

it suffices to set for $f$ a (nonzero) constant function. But

$$\mathcal{M}_g := \bigcap_{\xi \in \mathfrak{g}} \mathcal{M}_{\xi} = \bigcap_{j=1}^{n} \mathcal{M}_{\xi_j} \supset \mathcal{M}_s \setminus \{m_o\} = \mathcal{N}_s,$$  \hspace{1cm} (5.1.85)$$

where $\{\xi_j : j = 1, 2, \ldots n\}$ is a basis of $\mathfrak{g}$, 5.1.13, and $\mu_\omega$ is concentrated on states in $\mathcal{M}_g$,

$$\mu_\omega(\mathcal{M}_g) = \mu_\omega(\mathcal{M}) = 1, \quad \textrm{for any } \omega \in S_*(\mathfrak{M}_G).$$  \hspace{1cm} (5.1.86)$$

Let

$$F_{\xi} : \mathcal{M}_{\xi} \to \mathbb{R}, \quad m \mapsto F_{\xi}(m) := F_m(\xi) := \lim_{n} m(E_{\xi\Pi}(B_n)X_{\xi\Pi}), \quad (5.1.87)$$
what is a bounded continuous function on each $\mathcal{M}_{\xi_n}$, and due to monotonicity it is continuous on the whole $\mathcal{M}_{\xi}$. For $f$ in (5.1.80) we have:

$$m(E_{\xi n}(B_n)f(X_{\xi n})) = f(F_m(\xi)) \text{ for } m \in \mathcal{M}_{\xi_n},$$  

(5.1.88)

if for $\lambda = F_m(\xi)$ the value $f(\lambda)$ is defined. From (5.1.81), one sees that the functions $m \mapsto \chi_{\xi_n}(m)f(F_m(\xi))$ are in $L^1(\mathcal{M}, \mu_\omega)$. By an application of the Beppo-Levi theorem to their absolute values, we obtain:

The functions $F_{\xi}^*f \in L^1(\mathcal{M}, \mu_\omega)$; here it is

$$F_{\xi}^*f := f \circ F_{\xi} : \mathcal{M}_{\xi} \to \mathbb{R}, \quad m \mapsto f(F_{\xi}(m)) = f(F_m(\xi)).$$  

(5.1.89)

We have used here (5.1.80) and (5.1.81). After a subsequent application of the Lebesgue dominated convergence theorem we arrive at:

$$\omega(f(X_{\xi n})) = \mu_\omega(F_{\xi}^*f) := \int_\mathcal{M} f(F_m(\xi))\mu_\omega(dm).$$  

(5.1.90)

The relation (5.1.77) is valid due to (i). This means that the functions $f_1(\lambda) := \lambda, f_2(\lambda) := \lambda^2, \ (\lambda \in \mathbb{R})$, are both in $L^1(\mathbb{R}, \mu_\omega^2)$ for all $\xi \in \mathfrak{g}$ and for $f := f_j (j = 1, 2)$ (5.1.90) is valid. Hence $F_{\xi} \in L^2(\mathcal{M}, \mu_\omega)$ for all $\xi \in \mathfrak{g}$ and, due to (5.1.77), we have

$$(F_{\xi}, F_{\xi}) = (F_{\xi}, 1(1, F_{\xi}), \text{ for all } \xi \in \mathfrak{g}.  

(5.1.91)

The brackets denote here here the scalar product in $L^2(\mathcal{M}, \mu_\omega)$ and $1 \in L^2(\mathcal{M}, \mu_\omega)$ is the function identically equal to one: $1(m) := 1$ for all $m \in \mathcal{M}$. Applying the Schwarz inequality to (5.1.91), we obtain:

$$F_{\xi} = \text{const.} = (1, F_{\xi}) 1 = F_\omega(\xi) 1, \ \mu_\omega-\text{a.e. for all } \xi \in \mathfrak{g}.  

(5.1.92)

This means that the function

$$F_\omega : \mathcal{M}_0 \to \mathfrak{g}^*, \quad m \mapsto F_m,$$  

(5.1.93)

is constant $\mu_\omega$-almost everywhere, too. The restriction of $F_\omega$ to the set of normal states $\mathcal{N}_s$ separates points in $\mathcal{N}_s$ according to 5.1.13 and (5.1.87). Hence the set $F_\omega^{-1}(F_\omega) \subset \mathcal{M}_0$ contains at most one $m \in \mathcal{N}_s$. Due to continuity of $F_\omega$, the set $F_\omega^{-1}(F_\omega)$ is closed in $\mathcal{M}_0 = \mathcal{M}_0^\circ (:= \text{the interior of } \mathcal{M}_0)$, what implies measurability of $F_\omega^{-1}(F_\omega)$. Due to (5.1.92):

$$\mu_\omega(F_\omega^{-1}(F_\omega)) = \mu_\omega(\mathcal{M}) = 1.  

(5.1.94)

It is known, see e.g. [274], that for any $\omega \in \mathcal{S}(\mathcal{M}_G)$ there is a unique projector $s_\omega \in \mathcal{M}_G$ such that $\omega(x) = \omega(xs_\omega)$ for all $x \in \mathcal{M}_G$ and $\omega(x^*x) = 0$ implies $xs_\omega = 0$. The characteristic function in $C(\mathcal{M})$ corresponding to $s_\omega$ is supported by the clopen set $\text{supp } \mu_\omega \subset \mathcal{M}$. Since it is nonempty, it contains some $m \in \mathcal{M} \setminus \{m_0\} = \mathcal{N}_s$, and all these $m$'s are contained in $F_\omega^{-1}(F_\omega)$ due to (5.1.85). Hence the clopen set $\text{supp } \mu_\omega$ contains exactly one point of $\mathcal{M}_s$ which means,
5.1. MULTIPLE SYSTEMS

according to Proposition 5.1.16, that \( \text{supp} \mu_{\omega} \) is a one point subset of \( \mathcal{M}_* \) and \( s_{\omega} = E_{\mathfrak{g}}(F_{\omega}) \).

This proves the implication (i) \( \Rightarrow \) (ii).

\[ \square \]

5.1.20 Corollary. \( \sigma_G^* \mathcal{E}_\mathfrak{g} = \mathcal{E}_\mathfrak{g} \), i.e. \( \mathcal{E}_\mathfrak{g} \) is \( \sigma_G^* \)-invariant (:= '\( G \)-invariant').

Proof. According to (5.1.62) and Lemma 5.1.13, the set \( \mathcal{N}_* \) is \( G \)-invariant. The action of \( G \) (via \( \sigma_G^* \)) commutes with the mapping \( \omega (\in \mathcal{S}(\mathfrak{g}^1)) \mapsto \omega (\in \mathcal{S}_*(\mathfrak{M}_G)) \). Then the result is immediate after an application of 5.1.19.

\[ \square \]

5.1.21 Proposition. For any \( \omega \in \mathcal{S}_*(\mathfrak{M}_G) \), the corresponding probability Radon measure \( \mu_{\omega} \) on \( \mathcal{M} \) is supported by \( \mathcal{M}_* \):

\[ \mu_{\omega}(\mathcal{M}_*) = \mu_{\omega}(\mathcal{M}) = 1. \quad (5.1.95) \]

Proof. We can assume that \( s_G s_{\omega} = s_{\omega} \) for the support projector \( s_{\omega} \) of \( \omega \). We have, according to 5.1.16 (i), \( s_{\omega} = c(s_{\omega} \mathfrak{g}^*) \).

Due to normality of \( \omega \), it is

\[ 1 = \omega(s_{\omega}) = \text{l.u.b.}\{\omega(p_J) : p_J := \sum_{F \in J} E_{\mathfrak{g}}(F), \text{ finite } J \subset s_{\omega} \mathfrak{g}^*\}. \quad (5.1.96) \]

Let \( m_F \in \mathcal{M}_* \) (\( F \in \mathfrak{g}^* \), \( E_{\mathfrak{g}}(F) \neq 0 \)) be defined by \( m_F(E_{\mathfrak{g}}(F)) = 1 \). For any subset \( \mathcal{K} \subset \mathfrak{g}^* \), the open set (which is clopen for finite \( \mathcal{K} \))

\[ \mathcal{M}(\mathcal{K}) := \{m_F \in \mathcal{M}_* : F \in \mathcal{K}\}, \quad m_F \text{ is void if } E_{\mathfrak{g}}(F) = 0, \quad (5.1.97) \]

is \( \mu_{\omega} \)-measurable. But \( \omega(p_J) = \mu_{\omega}(\mathcal{M}(J)) \), and \( \mu_{\omega} \) is regular. Hence,

\[ 1 = \text{l.u.b.}\{\mu_{\omega}(\mathcal{M}(J)) : J \subset s_{\omega} \mathfrak{g}^* \text{ finite}\} \leq \mu_{\omega}(\mathcal{M}(s_{\omega} \mathfrak{g}^*)) \leq \mu_{\omega}(\mathcal{M}_*) \leq 1, \quad (5.1.98) \]

what proves (5.1.95).

\[ \square \]

5.1.22 Lemma. Any uniformly bounded function on \( \mathcal{M}_* \) with values in \( \mathbb{C} \) can be uniquely extended to a continuous function on \( \mathcal{M} \), i.e. the spectrum space \( \mathcal{M} \) of \( \mathfrak{M}_G \) is the Stone-Čech compactification of the discrete space \( \mathcal{M}_* \) of normal pure states on \( \mathfrak{M}_G \).

Proof. Since \( \mathcal{M}_* \) is discrete, \( C(\mathcal{M}_*) \) consists of all bounded complex valued functions on \( \mathcal{M}_* \). The Stone-Čech compactification of a normal topological space \( \mathcal{S} \) is a compact Hausdorff space \( \mathcal{S}' \) and a homeomorphism \( \tau \) of \( \mathcal{S} \) into \( \mathcal{S}' \) such, that \( \tau(\mathcal{S}) \) is dense in \( \mathcal{S}' \) and any \( f \in C(\mathcal{S}) \) can be continued to some \( \tilde{f} \in C(\mathcal{S}') \). It is clear, that the continuation \( \tilde{f} \) is uniquely determined by \( f \).

Let \( f \in C(\mathcal{M}_*) \), \( f \geq 0 \). For any \( \iota \in [0, \|f\|] \) (:= closed interval in \( \mathbb{R} \)) define (cf. (5.1.68))

\[ p_\iota := 0 \text{ for } \iota \notin \text{sp}(f) \text{ and (let } f(m_0) = 0): \]

\[ p_\iota := c(\{F_m \in \mathfrak{g}^* : f(m) = \iota, \ m \in \mathcal{M}_*\}), \quad \iota \in \text{sp}(f), \quad (5.1.99) \]

where \( \text{sp}(f) \) denotes the spectrum of \( f \). For any finite subset \( J \subset \text{sp}(f) \) define

\[ x_J := \sum_{\iota \in J} \iota p_\iota \in \mathfrak{M}_G. \quad (5.1.100) \]
The finite subsets \( J \) of \( sp(f) \) are directed by inclusion and the net \( \{ x_J : \ \text{finite} \ J \subset sp(f) \} \) is increasing. Any increasing net of selfadjoint elements of a \( W^* \)-algebra \( \mathcal{M} \) converges to its least upper bound in \( \mathcal{M} \), [274, 1.7.4]. Let \( x_f \in \mathcal{M}_G \) be the limit of \( \{ x_J \} \). We claim that the function \( f \in C(\mathcal{M}) \), \( \tilde{f}(m) := m(x_f) \) coincides with \( f \) on \( \mathcal{M}_* \).

Let \( m \in \mathcal{M}_* \). Then, due to normality of \( m \),

\[
\tilde{f}(m) = \text{l.u.b.}\{m(x_J) : \ \text{finite} \ J \subset sp(f)\} = \sum_{i \in J} \lambda_i m(p_i) = \text{l.u.b.}\{\sum_i \lambda_i m(p_i) : \ \text{finite} \ J \subset sp(f)\}. \tag{5.1.101}
\]

But \( m \in \mathcal{M}_* \) lies in support of the characteristic function \( m \mapsto m(p_i) \) iff \( f(m) = \lambda_i \), compare 5.1.16. Hence \( \tilde{f}(m) = f(m) \), what we intended to prove. \( \square \)

5.1.23 Lemma. Let, for \( \omega \in \mathcal{S}(\mathcal{N}_G) \), \( \mu_\omega \) be a finitely additive probability measure on \( \mathcal{N}_* \), supported by \( s_G \mathcal{G}_* \), \( \mu_\omega \) is \( \sigma \)-additive. Any \( \mu_\omega \) \( \omega \in \mathcal{S}(\mathcal{N}_G) \) is of the form \( F^*_\mathcal{G}_* \mu \) for some \( \sigma \)-additive probability Borel measure \( \mu \) on \( \mathcal{G}_* \) with at most countable supporting set in \( s_G \mathcal{G}_* \).

Proof. \( \mathcal{N}_* \) is mapped bijectively by \( F_\mathcal{G} \) onto \( s_G \mathcal{G}_* \) and \( \mu_\omega \) is supported by \( \mathcal{N}_* \) for all \( \omega \in \mathcal{S}(\mathcal{N}_G) \). Hence (i) is fulfilled for \( \mu := \mu_\omega \circ F_\mathcal{G}^{-1} \). Complete additivity of \( \mu_\omega \) (what is a consequence of normality of \( \omega \) ) leads then to the expression

\[
\mu_\omega = \sum_{m \in \mathcal{N}_*} \omega(E_\mathcal{G}(F_m)) \delta_m, \quad (\delta_m := \text{Dirac measure at } m). \tag{5.1.102}
\]

Hence at most countable number of coefficients \( \omega(E_\mathcal{G}(F_m)) \neq 0 \). This proves (i) \( \Rightarrow \) (ii) as well as the last assertion of the Lemma. Let

\[
\mu = \sum_{j \in \mathbb{Z}_+} \lambda_j \delta_{F_j}, \quad \text{with} \ \lambda_j \geq 0, \ \sum_j \lambda_j = 1, \ F_j \in s_G \mathcal{G}_*. \tag{5.1.103}
\]

Then \( F^*_\mathcal{G}_* \mu := \mu \circ F_\mathcal{G} \) is a Baire measure on \( \mathcal{N}_* \), hence represents a (normal) state \( \omega \) on \( \mathcal{N}_G \). The \( \sigma \)-additivity is clear. \( \square \)

5.1.24 Lemma. Let, for \( \omega \in \mathcal{S}(\mathcal{N}_G) \), \( \mu_\omega \) be the additive function of Borel subsets of \( \mathcal{G}_* \) defined in (5.1.71). Then \( \mu_\omega \) has a unique extension to a finitely additive probability measure on the set of all subsets of \( s_G \mathcal{G}_* \). Conversely, any finitely additive probability measure on \( s_G \mathcal{G}_* \) is of the form \( \mu_\omega \) for some \( \omega \in \mathcal{S}(\mathcal{N}_G) \).

Proof. For any subset \( K \subset \mathcal{G}_* \) define, (5.1.68),

\[
E_\mathcal{G}(K) := c(K) := \sum_{F \in K} E_\mathcal{G}(F). \tag{5.1.104}
\]
Then $E_\omega(K)$ is a projector in $\mathcal{M}_G$ and we can define

$$\mu_\omega^\omega(K) := \omega(E_\omega(K))$$

for any $K \subset \mathfrak{g}^*$ and any $\omega \in S(\mathcal{M}_G)$. \hfill (5.1.105)

It is easily to see that $\mu_\omega^\omega$ in (5.1.105) is the desired unique extension. For the proof of the second assertion, choose any finitely additive probability measure $\mu$ on $s_G\mathfrak{g}^*$, $\mu$ defined on all subsets $K$ of $s_G\mathfrak{g}^*$. Define a positive linear functional on $\mathcal{M}_G$, $\omega_\mu$, by its values on all projectors:

$$\omega_\mu(E_\omega(K)) := \mu(K),$$

compare 5.1.16. The von Neumann algebra $\mathcal{M}_G$ is generated by the set of all its projectors and (5.1.106) defines uniquely a state on $\mathcal{M}_G$. \hfill $\square$

5.1.25. Let us look what measures $\mu_\omega^\omega$ correspond to pure states $\omega \in \mathcal{M}$, which are not normal. From the character property of pure states we have $\omega(E_\omega(K_1 \cap K_2)) = \omega(E_\omega(K_1))\omega(E_\omega(K_2))$ what together with finite additivity gives:

$$K \subset \mathfrak{g}^* \Rightarrow \mu_\omega^\omega(K) \in \{0, 1\}. \hfill (5.1.107)$$

Remember that $\text{supp} \mu_\omega^\omega \subset s_G\mathfrak{g}^*$. Any finitely additive measure $\mu$ on $s_G\mathfrak{g}^*$ satisfying (5.1.107) corresponds to a pure state $\omega_\mu \in \mathcal{M}$. It determines also an ultrafilter on $s_G\mathfrak{g}^*$ consisting of all subsets $K$ for which it is $\mu(K) = 1$. This is clearly a bijection between the set of all ultrafilters on $s_G\mathfrak{g}^*$ and the set of pure states

$$\mathcal{E}S(\mathcal{M}_G) = \mathcal{N}.$$  

Remember that to any $m \in \mathcal{M}$ corresponds the Dirac measure $\delta_m$ on $\mathcal{M}$ which is concentrated at a point $m$. For a nonnormal $m$ the measure $\mu_\omega^m$ is not concentrated at any point in $\mathfrak{g}^*$.

5.1.26. Let us keep in mind that we have associated with any state $\omega \in S(\mathfrak{A}^\Pi)$ a state (equally denoted) $\omega \in S(\mathcal{M}_G)$ which is the restriction to $\mathcal{M}_G$ of the unique $w^*$-continuous extension to $(\mathfrak{A}^\Pi)^{**}$ of $\omega \in S(\mathfrak{A}^\Pi)$. Such an $\omega \in S(\mathcal{M}_G)$ is necessarily normal: $\omega \in S_*(\mathcal{M}_G)$, and the corresponding measure $\mu_\omega^\omega := \mu_\omega \circ F^{-1}$ is purely atomic, 5.1.23. This reflects that fact that the described procedure maps into $S(\mathcal{M}_G)$ only such states on $(\mathfrak{A}^\Pi)^{**}$ which are describable by density matrices in $\mathcal{L}(P_G \mathcal{H}_\Pi)$.

Any state on $\mathcal{M}_G$ can be, on the other hand, extended to some states on $(\mathfrak{A}^\Pi)^{**}$ (not normal - in general) and these determine their restrictions to $\mathfrak{A}^\Pi$ considered as a subalgebra of its bidual. In this way, we can obtain also those states on $P_G \mathfrak{A}^\Pi$ which are not expressible by density matrices. Hence to general finitely additive probability measures on $\mathcal{N}_*$ "correspond", in some many-to-many way, arbitrary states on $P_G \mathfrak{A}^\Pi$. We intend now to change our ascription of states on $\mathcal{M}_G$ to arbitrary states on $\mathfrak{A}^\Pi$ in such a way, that any state on $P_G \mathfrak{A}^\Pi$ will be mapped into $S(\mathcal{M}_G)$ (and not onto $m_\omega \in \mathcal{M}_*$ as before).

5.1.27. Quasilocal structure of $\mathfrak{A}^\Pi$: The algebra $\mathfrak{A}^\Pi$ has a natural quasilocal structure in the sense of 1.4.2. It is generated by local algebras $\mathfrak{A}_e := \mathfrak{A}^N$ ($N \in \Pi$), (1.4.1), where, in the
notations of 5.1.3, \( \mathfrak{A}^N \) is generated by \( \pi_j(y) \ (y \in \mathcal{L}(\mathcal{H}), \ j = 1, 2, \ldots, N) \) and is isomorphic to \( \mathcal{L}(\mathcal{H}_N) \). \( \mathcal{H}_N \) is here the \( N \)-fold tensor product of the Hilbert space \( \mathcal{H} \), (5.1.10). Denote by \( \mathfrak{A}_L \) the set of all finite linear combinations of finite products of arbitrary elements \( y \in \mathfrak{A}^N \) for any finite \( N \). The algebra \( \mathfrak{A}_L := \cup_{\text{finite } N} \mathfrak{A}^N \) is called the 'local algebra' and its elements are 'local observables'. The norm closure of \( \mathfrak{A}_L \) is \( \mathfrak{A}^\Pi \) = the algebra of quasilocal observables of our system.

A locally normal state \( \omega \in \mathcal{S}(\mathfrak{A}^\Pi) \), i.e. a state the restriction of which to any local subalgebra \( \mathfrak{A}^N \) is normal (cf. 1.4.3), can be calculated (with a use of natural isomorphisms) on all the elements \( x \in \mathfrak{A}^N \subset \mathfrak{A}^\Pi \) with the help of density matrices \( \rho^\omega_N \ (N = 1, 2, \ldots) \) on \( \mathcal{H}_N \) via the usual formula

\[
\omega(x) = Tr(\rho^\omega_N x), \quad x \in \mathcal{L}(\mathcal{H}_N),
\]

where we have identified \( \mathfrak{A}^N \) with \( \mathcal{L}(\mathcal{H}_N) \). Let \( \mathcal{S}_L(\mathfrak{A}^\Pi) := \mathcal{S}_L \) denotes the set of all locally normal states on \( \mathfrak{A}^\Pi \). The states expressible (globally) by a density matrix in the defining representation of \( \mathfrak{A}^\Pi \) in \( \mathcal{H}_\Pi \) are locally normal. \( \mathfrak{A}^\Pi \) is simple, [53, 2.6.20].

5.1.28 Example. We shall illustrate here the fact that a strongly continuous one parameter group of unitaries \( \exp(itP) \) acting on a Hilbert space \( \mathcal{H} \) need not be continuous in certain other representations of \( \mathcal{L}(\mathcal{H}) \).

Let \( \mathfrak{A} := \mathcal{L}(\mathcal{H}) \) be the considered \( W^* \)-algebra, \( \mathcal{H} := L^2(\mathbb{R}) \), and \( Q \) (resp. \( P \)) be the selfadjoint operator on \( \mathcal{H} \) defined on \( \varphi \in C_0^1(\mathbb{R}) \) by \( (Q\varphi)(\lambda) := \lambda \varphi(\lambda) \) (resp. \( (P\varphi)(\lambda) := -i \frac{d}{d\lambda} \varphi(\lambda) \)), \( \lambda \in \mathbb{R} \). Let \( \mathfrak{M} \) be the maximal commutative \( W^* \)-algebra in \( \mathcal{L}(\mathcal{H}) \) generated by \( \exp(itQ) \), \( t \in \mathbb{R} \). Let \( \chi_\lambda \) be the pure state on \( \mathfrak{M} \) determined by

\[
\chi_\lambda(\exp(itQ)) := \exp(it\lambda), \quad t \in \mathbb{R}.
\]

Let \( \omega_\lambda \) be an extension of \( \chi_\lambda \) onto the whole \( W^* \)-algebra \( \mathfrak{A} \). We claim that the function

\[
t \mapsto \omega_\lambda(\exp(itP)), \quad t \in \mathbb{R},
\]

is discontinuous, hence the group \( \pi_\lambda(\exp(itP)) \) of unitaries in the cyclic representation of \( \mathfrak{A} \) corresponding to the state \( \omega_\lambda \in \mathcal{S}(\mathfrak{A}) \) is not strongly continuous. Since \( \chi_\lambda \) is pure, it is a character on \( \mathfrak{M} \). Consequently for any projector \( q \in \mathfrak{M} \) it is

\[
\chi_\lambda(q) = [\chi_\lambda(q)]^2, \ i.e. \chi_\lambda(q) \in \{0, 1\}, \ q^* = q^2 = q \in \mathfrak{M}.
\]

We obtain from the Schwarz inequality, for any \( x \in \mathfrak{A} \),

\[
\omega_\lambda(x) = \omega_\lambda(qx) = \omega_\lambda(xq), \quad \text{for all } \{q = q^* = q^2 : q \in \mathfrak{M}, \ \chi_\lambda(q) = 1\}.
\]

Any element \( z \in \mathfrak{M} \) can be expressed as a norm limit of finite linear combinations of projectors \( q \in \mathfrak{M} \). Since the product \( z \mapsto xz \) is norm-continuous and the state \( \omega_\lambda \) is also continuous in the norm of \( \mathfrak{A} \), we obtain from (5.1.112):

\[
\omega_\lambda(xz - zx) \equiv \omega_\lambda([x, z]) = 0, \quad \forall x \in \mathfrak{A}, \ \text{and} \ \forall z \in \mathfrak{M}.
\]
Due to CCR we have

\[ [\exp(itP), \exp(i\tau Q)] = (e^{it\tau} - 1) \exp(i\tau Q) \exp(itP), \]

and after the substitution to (5.1.113):

\[ 0 = (e^{it\tau} - 1) \omega_\lambda(\exp(i\tau Q) \exp(itP)). \]

The relation (5.1.115) is valid for all real \( t \) and \( \tau \). From an application of (5.1.113) to 

\[ \omega_\lambda(\exp(-i\tau Q)[\exp(itP), \exp(i\tau Q)]) = \omega_\lambda(\exp(-i\tau Q) \exp(itP) \exp(i\tau Q)) - \omega_\lambda(\exp(itP)) \]

we obtain the invariance of \( \omega_\lambda \) with respect to the group \( \sigma^* \) of affine isometries of \( \mathcal{S}(\mathfrak{A}) \),

\[ \sigma^*_\tau \omega(x) := \omega(\exp(-i\tau Q)x \exp(i\tau Q)), \quad \tau \in \mathbb{R}, \quad x \in \mathfrak{A}. \] (5.1.116)

This leads, together with the formula (4.1.9), to

\[ \omega_\lambda(\exp(itP)) = e^{it\tau} \omega_\lambda(\exp(itP)) \quad \text{for all } t, \tau \in \mathbb{R}, \] (5.1.117)

what implies the discontinuity of (5.1.110).

The obtained formulas show also uniqueness of the extension \( \omega_\lambda \) of \( \chi_\lambda \) to the CCR-subalgebra of \( \mathfrak{A} \) defined as the norm closed algebra generated by \( \exp(i\tau Q) \) and \( \exp(itP) \) (\( t, \tau \in \mathbb{R} \)).

5.1.29. We shall now change the definition 5.1.12 of the macroscopic algebra of the system \( (\mathfrak{A}^\Pi, \sigma_G) \) in such a way that a larger subset of states from \( \mathcal{S}(\mathfrak{A}^\Pi) \) will be mapped onto probability measures on \( \mathfrak{g}^* \) than it was before, according to the ascription from 5.1.14. In the notations from 5.1.3 and 5.1.4, let

\[ X_{\xi N} := \frac{1}{N} \sum_{j=1}^{N} \pi_j(X_{\xi}), \quad N = 1, 2, \ldots, \xi \in \mathfrak{g}. \] (5.1.118)

Then the elements \( \exp(itX_{\xi N}) \in \mathfrak{A}^N \) (\( t \in \mathbb{R} \)) are represented in the defining representation of \( \mathfrak{A}^\Pi \) in \( \mathcal{H}_\Pi \) by strongly continuous groups converging with \( N \to \infty \) in the strong operator topology on the \( G \)-invariant subspace \( P_G \mathcal{H}_\Pi \) of \( \mathcal{H}_\Pi \) to strongly continuous central subgroups of \( P_G \mathfrak{B}^\# \),

\[ s-\lim_{N} \exp(itX_{\xi N})P_G = \exp(itX_{\xi \Pi})P_G, \] (5.1.119)

see 5.1.7, 5.1.8 and 5.1.11. The algebra \( \mathfrak{M}_G \) of macroscopic observables was built from spectral projectors \( E_{\xi \Pi}^\# \) of \( X_{\xi \Pi} \)'s mapped into the center 3 of the bidual \( (\mathfrak{A}^\Pi)^{**} \). We want to generalize this construction. We shall identify the bidual \( (\mathfrak{A}^\Pi)^{**} \) with the weak closure of the universal representation of \( \mathfrak{A}^\Pi \) (cf. [274, Def.1.16.5],[235, 3.7.6]). Let \( p_G \) be the l.u.b. of all such projectors \( p \in 3 \), for which the limits in \( \sigma((\mathfrak{A}^\Pi)^{**}, (\mathfrak{A}^\Pi)^*) \) – topology:

\[ \exp(itX_{\xi \Pi})p_G := \sigma-\lim_{N} \exp(itX_{\xi N})p_G, \quad \forall \xi \in \mathfrak{g}. \] (5.1.120)
exist (with \( p_G \rightarrow p \)). The symbol \( X_{\xi \Pi} \) denotes here a selfadjoint operator acting on the subspace \( p_G \mathcal{H}_u \) of the space \( \mathcal{H}_u \) – the space of universal representation of \( \mathfrak{A}^\Pi \). Here it is assumed, of course, that the groups \( t \mapsto \exp(itX_{\xi N})p_G \) are strongly continuous for all \( N \in \Pi \). It is clear from the definitions of \( X_{\xi N} \) and \( \sigma_G \), 5.1.5, that

\[
\sigma_G(p_G) = p_G. \tag{5.1.121}
\]

The convergence in (5.1.120) means the convergence \( X_{\xi N} \rightarrow X_{\xi \Pi} \) of selfadjoint operators on \( p_G \mathcal{H}_u \) in the strong-resolvent sense, [262]. From

\[
[\exp(itX_{\xi N}), \ y] = \left( \exp \left( \frac{it}{N} \sum_{j=1}^K \pi_j(X_\xi) \right) y \exp \left( -\frac{it}{N} \sum_{k=1}^K \pi_k(X_\xi) \right) - y \right) e^{itX_{\xi N}}, \tag{5.1.122}
\]

which is valid for all \( y \in \mathfrak{A}^K \) (\( K \in \Pi \)) and \( \xi \in \mathfrak{g} \), \( t \in \mathbb{R} \), as well as from the assumed continuity of \( p_G \exp(itX_{\xi N}) \) we conclude that the limit \( p_G \exp(itX_{\xi \Pi}) \in (\mathfrak{A}^\Pi)^{**} \) belongs to the center \( \mathfrak{3} \) of \( (\mathfrak{A}^\Pi)^{**} \). Let now the \( \Pi \)-macroscopic algebra of \( G \)-definiteness of \( (\mathfrak{A}^\Pi, \sigma_G) \) be defined as the von Neumann subalgebra \( \mathfrak{M}^\Pi_G \) of the center \( \mathfrak{3} \) generated by all the spectral projectors \( E_{\xi \Pi}(B) \) (Borel \( B \subset \mathbb{R} \) and \( \xi \in \mathfrak{g} \)) of operators \( X_{\xi \Pi} \) in \( p_G \mathcal{H}_u \) (we hope that no confusion arises from the keeping an old notation for new objects!). The algebra \( \mathfrak{M}^\Pi_G \) is obtained from \( \mathfrak{M}^\Pi_G \) by adjoining to it the identity \( I \) of \( \mathfrak{3} \); it will be called the \( \Pi \Pi \)-macroscopic algebra of \( (\mathfrak{A}^\Pi, \sigma_G) \). The relation between \( \mathfrak{M}^\Pi_G \) and the previously introduced \( \mathfrak{M}_G \), 5.1.12, is clear without any proof:

**5.1.30 Lemma.** \( \mathfrak{M}_G = s_G \mathfrak{M}^\Pi_G = s_G \mathfrak{M}^\Pi_G = s_G \mathfrak{M}_G \), where the projector \( s_G \in \mathfrak{3} \) was introduced in 5.1.11.

**5.1.31.** We shall use concepts and notations connected with the usage of \( \mathfrak{M}^\Pi_G \) in analogy to those connected with \( \mathfrak{M}_G \), as they were introduced above. Let e.g., \( B \subset \mathfrak{g}^* \) be a Borel set (with respect to the usual topology of a finite dimensional vector space), and \( \xi_j \) \((j = 1, 2, \ldots n)\) form a basis of \( \mathfrak{g} \). Let

\[
\xi_j B := \{ \lambda \in \mathbb{R} : \lambda = F(\xi_j), F \in B \} \tag{5.1.123}
\]

be the projection of \( B \) onto the \( j \)-th coordinate axis of the dual frame. If \( B \) has the form

\[
B = \{ F \in \mathfrak{g}^* : F(\xi_j) \in \xi_j B, \forall j \in \{1,2,\ldots n := \dim G\} \}, \tag{5.1.124}
\]

then we set

\[
E^\Pi_{\xi_j}(B) := E_{\xi_1 \Pi}(\xi_1 B)E_{\xi_2 \Pi}(\xi_2 B)\ldots E_{\xi_n \Pi}(\xi_n B). \tag{5.1.125}
\]

The \( W^* \)-algebra \( \mathfrak{M}^\Pi_G \) is generated by the projectors \( E^\Pi_{\xi_j}(B) \) from (5.1.125) & (5.1.124), and by the unit \( I \in \mathfrak{3} \).

The algebra \( \mathfrak{M}^\Pi_G \), contrary to \( \mathfrak{M}_G \), cannot be built from projectors (5.1.125) corresponding to one point sets \( B := \{ F \} \) \((F \in \mathfrak{g}^*)\) only. This can be seen as follows: Choose a
5.1. MULTIPLE SYSTEMS

probability Borel measure \( \mu \) on \( s_G g^* \), in the old notation from 5.1.16, such that any point (Dirac) measure is singular with respect to it: \( \mu(\{F\}) = 0 \) for all \( F \in g^* \). Choose a product vector \( \Psi(F) \in E_\#(F)P_G H_\Pi \), one and only one for each such \( F \in g^* \), for which \( E_\#(F) \neq 0 \). Denote by \( \omega_F := \omega^{\Psi(F)} \) the corresponding state on \( A^\Pi \). Assume, that all the functions

\[
F \mapsto \omega^F(x), \quad x \in A^\Pi,
\]

are \( \mu \)-measurable. This last assumption is trivially fulfilled, if \( \mu \) is concentrated on an \( Ad^*(G) \) orbit \( G \cdot F \subset g^* \) and \( \omega^g := \sigma_g^* \omega^F \). Define then the state \( \omega_\mu \in S(A^\Pi) \) by

\[
\omega_\mu(x) := \int g^* \omega^F(x) \mu(dF). \tag{5.1.127}
\]

In this way, we can construct \textbf{states} \( \omega_\mu \) the \textbf{central supports} \( s_\mu \in 3 \) of which are \textbf{contained in} \( p_G \), \( s_\mu p_G = s_\mu \), but \( s_\mu s_G = 0 \), as well as \( s_\mu E^\Pi_g(F) = 0 \) for all \( F \in g^* \), in \( M_G^\Pi \).

The last considerations show to us that \( M_G \) and \( M_G^\Pi \) are different from one another. The \( W^* \)-subalgebra of \( M_G^\Pi \) generated by all \( E^\Pi_g(F) := E^\Pi_g(\{F\}) \) (\( F \in g^* \)) is naturally isomorphic to \( M_G \). Hence \( M_G^\Pi \) is larger than \( M_G \) which can be injected into \( M_G^\Pi \) via the last mentioned isomorphism.

5.1.32. Let us now introduce the mapping \( p_M \):

\[
p_M : S(A^\Pi) \to S_s(M_G^\Pi), \quad \omega \mapsto p_M \omega, \tag{5.1.128}
\]

where \( p_M \omega \) is the \textbf{restriction} to \( M_G^\Pi \) of the canonical extension of the state \( \omega \in S(A^\Pi) \) to the normal state on \( (A^\Pi)^{**} \). Any state \( \omega \in S(A^\Pi) \) (resp. \( \omega \in S(M_G^\Pi) \)) can be uniquely decomposed as

\[
\omega = \omega(p_G)p_G \omega + \omega(I-p_G) \omega_o. \tag{5.1.129}
\]

where the symbols \( p_G \omega(x) \) and \( \omega_o(x) \) are given by

\[
p_G \omega(x) := \frac{1}{\omega(p_G)} \omega(x p_G), \quad \omega_o(x) := \frac{1}{\omega(I-p_G)} \omega(x(I-p_G)).
\]

Hence for \( \omega(I-p_G) \neq 0 \) it is

\[
p_M \omega_o = m_o := \text{the pure state in } S(M_G^\Pi) \text{ supported by the minimal projector } I-p_G \in M_G^\Pi.
\]

Let

\[
S_g^\Pi := \{ \omega \in S(A^\Pi) : \omega(p_G) = 1 \}. \tag{5.1.130}
\]

In other words: \( S_g^\Pi = p_G S(A^\Pi) \). For \( \omega \in S_g^\Pi \) one has \( p_M \omega \in S_s(M_G^\Pi) \). Conversely, each state in \( S_s(M_G^\Pi) \) is of the form \( p_M \omega \) for some states \( \omega \in S_g^\Pi \).

5.1.33 Lemma. The projector-valued additive function of intervals in \( g^* \) introduced in (5.1.125) can be extended to a unique projector-valued measure \( E^\Pi_g : B \mapsto E^\Pi_g(B) \) defined on all Borel sets \( B \) in \( g^* \).
Proof. The mapping
\[ w : g \rightarrow \mathcal{L}(p_G \mathcal{H}_u), \; \xi \mapsto w(\xi) := \exp(iX_{\xi^*})p_G, \]
see (5.1.120), is strongly continuous unitary representation of the abelian group \( g \) (group multiplication is here the vector addition) in the subspace \( p_G \mathcal{H}_u \) of the Hilbert space \( \mathcal{H}_u \) of the universal representation of \( \mathfrak{A}^\Pi \). This can be seen with a help of linearity of the mapping
\[ \xi \mapsto X_{\xi^*}, \; \xi \in g. \]  

According to the SNAG-theorem ([266, Chap. X], [262, Thm.VIII.12], [120, Chap. IV]), there is unique projection measure \( E^\Pi_g \) on the dual group \( \hat{g} \) of \( g \) representing this unitary representation in the standard fashion. The linear space \( g^* \) can be identified with the group \( \hat{g} \) of characters by the bijection associating with any \( F \in g^* \) the character \( \xi \mapsto \exp(iF(\xi)) \) on \( g \). It is clear that the restriction of \( E^\Pi_g \) on intervals in \( g^* \) coincides with (5.1.125). \( \square \)

5.1.34 Lemma. All the nonzero projectors of the form \( E^\Pi_g(F) := E_g(\{F\}) \), \( F \in g^* \), are minimal projectors in \( \mathfrak{N}_G^\Pi \) and all minimal projectors in \( \mathfrak{N}_G^\Pi \) are of this form.

Proof. Let \( q \in \mathfrak{N}_G^\Pi \) be a minimal projector. Since \( q \in \mathfrak{Z} \), there is a state \( \omega \in \mathcal{S}(\mathfrak{A}^\Pi) \), the central projector of which is \( s_\omega \leq q \). Choose such an \( \omega \). Then \( \omega(x) = \omega(xs_\omega) = \omega(xq) \) for all \( x \in \mathfrak{A}^\Pi \), and due to continuity properties of products in \( (\mathfrak{A}^\Pi)^{**} \) as well as of the normal extension \( \omega \in \mathcal{S}_*(\mathfrak{A}^\Pi)^{**} \), the same is true for all \( x \in (\mathfrak{A}^\Pi)^{**} \). The minimality of \( q \) in \( \mathfrak{N}_G^\Pi \) implies that one of the following possibilities (i) or (ii) is valid
\[ (i) \ qE^\Pi_g(B) = q, \quad (ii) \ qE^\Pi_g(B) = 0 \]
for any Borel \( B \subset g^* \). Let us define a probability Borel measure \( \mu^\omega_g \) on \( g^* \) corresponding to the \( \omega \in \mathcal{S}_G^\Pi \):
\[ \mu^\omega_g(B) := p_M \omega(E^\Pi_g(B)), \; \text{for all} \; B \subset g^*. \]

We see from (5.1.133) that for the chosen \( \omega \) the values of \( \mu^\omega_g \) lie in the two point set \( \{0, 1\} \subset \mathbb{Z}_+ \). Each of the projection measures \( E_{\xi^*} (\xi \in g) \) and \( E^\Pi_g \) are \( \sigma \)-additive, hence \( \mathfrak{N}_G^\Pi \) is generated by those \( E^\Pi_g(B) \) which correspond to bounded Borel subsets \( B \) of \( g^* \). Hence \( \mu^\omega_g \) is concentrated on a compact subset of \( g^* \): \( \mu^\omega_g(B_0) = 1 \) for some compact \( B_0 \). The \( \sigma \)-additivity of \( \mu^\omega_g \) implies then that \( \mu^\omega_g \) is concentrated on a one-point set \( F_\omega \in B_0 \):
\[ \mu^\omega_g(\{F_\omega\}) = p_M \omega(E^\Pi_g(F_\omega)) = 1. \]
This implies \( s_\omega \leq E^\Pi_g(F_\omega) \), and, due to (5.1.133) and due to our choice of \( s_\omega \):
\[ q \leq E^\Pi_g(F_\omega). \]

According to the definition of \( \mathfrak{N}_G^\Pi \) in 5.1.29, \( q \) can be approximated, in \( \sigma(\mathfrak{N}_G^\Pi, \mathfrak{N}_G^{**}) \) topology, by a net \( j \mapsto E^\Pi_g(B_j) \), where \( F_\omega \in B_j \) for all \( j \), due to (5.1.136). Coming to the Gel’fand representation \( C(\mathcal{N}^\Pi) \) of \( \mathfrak{N}_G^\Pi \) and considering that \textbf{clopen sets in the spectrum space} \( \mathcal{N}^\Pi \)
form a basis of topology, e.g. 5.1.14 and [274], we see that the sets in \( N^\Pi \) corresponding to the projectors \( E^\Pi_g(B_j) \) have in their intersection exactly one point \( m_q \in N^\Pi \) corresponding to the minimal projector \( q \). All of \( E^\Pi_g(B_j) \) contain, however, also \( E^\Pi_g(F_\omega) \). This proves that \( q = E^\Pi_g(F_\omega) \).

5.1.35 Lemma. If \( \omega \in S(\mathfrak{A}_g^\Pi) \) is pure or factor state, then also \( p_M^\omega \in S_\ast(\mathfrak{M}^\Pi_G) \) is pure.

Proof. Verbally the same proof as that of 5.1.17, with \( \mathfrak{M}_G \cong \mathfrak{M}^\Pi_G \).

5.1.36 Definitions. The generalized G-macroscopic phase space is the topological space \( \mathcal{M}^G := \mathfrak{g}^* \cup \{m_\circ\} \) consisting of the finite (n-)dimensional topological vector space \( \mathfrak{g}^* \) with the canonical symplectic forms defined on each orbit of the \( \text{Ad}^\ast(G) \)-action and of an isolated point \( m_\circ \). A state on \( \mathcal{M}^G \) is any probability \( \sigma \)-additive Borel measure \( \mu \) on \( \mathcal{M}^G \). We shall associate with any \( \omega \in S(\mathfrak{A}_g^\Pi) \) the G-macroscopic state on \( \mathcal{M}^G \) determined by the measure

\[
\mu^\omega_g(B) := \omega(E^\Pi_g(B \setminus \{m_\circ\})) + \omega(I - p_G)\delta_{m_\circ}(B), \quad \text{for Borel } B \subset \mathcal{M}^G, \tag{5.1.137}
\]

where on the right hand side \( \omega \) means the normal extension of the state on \( \mathfrak{A}_g^\Pi \) to a normal state on \( (\mathfrak{A}_g^\Pi)^{**} \) and \( \delta_m \) \( (m \in \mathcal{M}^G) \) means the Dirac measure concentrated on \( \{m\} \). It is clear that every normal state \( \omega \in S(\mathfrak{M}_G^\Pi) \) can be transformed also into a state on \( \mathcal{M}^G \) by the formula (5.1.137) and that its image \( \mu^\omega_g \) uniquely determines \( \omega \in S(\mathfrak{M}_G^\Pi) \). It is also clear that the state on \( \mathcal{M}^G \) corresponding to \( p_M^\omega \), 5.1.32, in this way, coincides with \( \mu^\omega_g \). The association \( \omega \mapsto \mu^\omega_g \) is G-equivariant, i.e.

\[
\mu^g_\ast \omega = \sigma^\ast_g \mu^\omega, \quad \text{with } g \cdot \omega := \sigma^\ast_g \omega, \quad g \in G, \tag{5.1.138}
\]

and with

\[
\sigma^\ast_g \mu(B) := \mu(\text{Ad}^\ast(g^{-1})(B \setminus \{m_\circ\})) + \mu(\{m_\circ\} \cap B), \tag{5.1.139}
\]

for all \( g \in G \) and all Borel \( B \subset \mathcal{M}^G \). We shall use also \( g \cdot \mu := \sigma^\ast_g \mu \). This follows from the transformation properties of \( X_\xi^\Pi \)'s and from

\[
\sigma^\ast_g E^\Pi_g(B) = E^\Pi_g(\text{Ad}^\ast(g)B), \tag{5.1.140}
\]

compare 5.1.15.

Let us redefine some symbols introduced in 5.1.18. Let, (5.1.130),

\[
\mathcal{S}_g^d := \{\omega \in \mathcal{S}_g^\Pi : \xi \in L^1(\mathcal{M}^G, \mu^\omega_g), \quad \forall \xi \in \mathfrak{g}\}, \tag{5.1.141}
\]

where \( \xi \) is considered as the linear function \( F \mapsto \xi(F) := F(\xi) \) on \( \mathfrak{g}^* \) (\( \Theta F \)). Similarly, we shall define now G-macroscopically pure states to be elements \( \omega \in \mathcal{E}_g \subset S(\mathfrak{A}_g^\Pi) \), where

\[
\mathcal{E}_g := \{\omega \in \mathcal{S}_g^d : \mu^\omega_g(\xi^2) = [\mu^\omega_g(\xi)]^2, \quad \forall \xi \in \mathfrak{g}\}. \tag{5.1.142}
\]

Using (5.1.91) and (5.1.92), we can see that the Proposition 5.1.19 can be replaced by: \( \omega \in \mathcal{E}_g \iff \mu^\omega_g = \delta_F \) for some \( F \in \mathfrak{g}^* \).
5.1.37 Definitions. A Poisson manifold \( \mathcal{M} \) is a differentiable \( C^\infty \)-manifold endowed with a bilinear mapping \( (f; g) \rightarrow \{f, g\} \) of couples of infinitely differentiable real functions \( f, g \in C^\infty(\mathcal{M}, \mathbb{R}) \) into \( C^\infty(\mathcal{M}, \mathbb{R}) \), the Poisson bracket, satisfying properties 1.3.5 (i)+(ii)+(iii)+(iv), i.e. the nondegeneracy 1.3.5(v) is not required. Due to 1.3.5(iv), the Poisson bracket \( \{f, g\} \) depends on \( df \) and \( dg \) only, and can be uniquely expressed as the value of a two-contravariant tensor field \( \lambda \) on these one forms:

\[
\lambda(df, dg) := \{f, g\}. \tag{5.1.143}
\]

To any \( f \in C^\infty(\mathcal{M}, \mathbb{R}) \) corresponds then a unique vector field \( \sigma_f \) on \( \mathcal{M} \) satisfying:

\[
dg(\sigma_f) := \lambda(df, dg), \quad \text{for all } g \in C^\infty(\mathcal{M}, \mathbb{R}). \tag{5.1.144}
\]

\( \sigma_f \) is the Hamiltonian vector field on \( \mathcal{M} \) with the Hamiltonian function \( f \).

With \( \mathcal{M} := \mathfrak{g}^* \), the cotangent space \( T^*_G \mathfrak{g}^* \) can be naturally identified, for any \( F \in \mathfrak{g}^* \), with the Lie algebra \( \mathfrak{g} \) of \( G \). Then, with this identification, \( df \in \mathfrak{g}^* \) for any \( f \) and \( F \). Then the Poisson bracket

\[
\{f, g\}(F) := -F([d_F f, d_F g]), \tag{5.1.145}
\]

where on the right hand side is the value of \( F \in \mathfrak{g} \) on the Lie algebra commutator in \( \mathfrak{g} \), defines a natural Poisson structure on \( \mathfrak{g}^* \). In this way, also \( \mathcal{M}^G \) is, naturally, a Poisson manifold. Hamiltonian vector fields \( \sigma_f \) are tangent to orbits of \( \text{Ad}^*(G) \)-action of \( G \) on \( \mathfrak{g}^* \) at any point \( F \in \mathfrak{g}^* \), compare [212]. The restriction of the Poisson structure (5.1.145) to any \( \text{Ad}^*(G) \)-orbit is the canonical symplectic structure on it.

5.1.38 Theorem. Let the system \( (\mathfrak{A}^\Pi, \sigma_G) \) be defined by (5.1.21) and (5.1.25). Let \( \mathfrak{M}^\Pi_G \) be the commutative \( \sigma_G \)-invariant \( W^* \)-subalgebra of \( \mathfrak{J} \) (:= the center of \( (\mathfrak{A}^\Pi)^{**} \)) defined in 5.1.29. Let \( p_M : \mathcal{S}(\mathfrak{A}^\Pi) \rightarrow \mathcal{S}_*(\mathfrak{M}^\Pi_G) \) be the mapping (5.1.128). We shall write also

\[
p_M \omega := \mu^\omega_G \tag{5.1.137},
\]

due to the existence of canonical embedding of \( \mathcal{S}_*(\mathfrak{M}^\Pi_G) \) into the space of probability Radon measures on \( \mathcal{M}^G \). Then:

(i) \( p_M \) is affine, \( \sigma((\mathfrak{A}^\Pi)^*, (\mathfrak{A}^\Pi)^{**}) = \sigma((\mathfrak{M}^\Pi_G)^*, \mathfrak{M}^\Pi_G) \)-continuous surjection onto \( \mathcal{S}_*(\mathfrak{M}^\Pi_G) := \) the set of all normal states on \( \mathfrak{M}^\Pi_G \);

(ii) \( p_M \) is \( G \)-equivariant, (5.1.138);

(iii) Let \( \mathcal{S}_F := \{\omega \in \mathcal{S}(\mathfrak{A}^\Pi) : \mu^\omega_{\mathfrak{g}} = \delta_F\} \), (here \( F \in \mathfrak{g}^* \), \( \delta_F \) is the Dirac measure concentrated at \( F \)). Then \( \mathcal{S}_F \subset \mathcal{E}_g \), (5.1.142), and \( \mathcal{S}_F \) is a weakly closed convex face\(^4\) in \( \mathcal{S}(\mathfrak{A}^\Pi) \);

(iv) \( \omega \in \mathcal{E}_g \) implies \( \mu^\omega_{\mathfrak{g}} = \delta_F \) for \( F = F_\omega \in \mathfrak{g}^* \), and for any factor-state \( \omega \in \mathcal{S}(\mathfrak{A}^\Pi) \) it is \( \mu^\omega_{\mathfrak{g}} = \delta_m \) for some \( m \in \mathcal{M}^G \);

\(^4\)A face \( S \) of a compact convex set \( K \) is defined to be a subset of \( K \) with the property that if \( \omega = \sum_{i=1}^n \lambda_i \omega_i \) is a convex combination of elements \( \omega_i \in K \) such that \( \omega \in S \) then \( \omega_i \in S \), \( \forall i = 1, 2, \ldots n \).
(v) Let $\mu_\omega$ be the canonical measure on the spectrum space $\mathcal{M}^\Pi$ of $\mathfrak{M}^\Pi_G = C(\mathcal{M}^\Pi)$ corresponding to the state $p_M \omega \in \mathcal{S}(\mathfrak{M}^\Pi_G)$, $\omega \in \mathcal{S}(\mathfrak{A}^\Pi)$. Then there is a canonically defined $\mu_\omega$-measurable function $\hat{\omega}(m) =: \omega_m$ (spaces are taken with their $w^*$-topologies) such that the restriction $r_M \omega_m = m \in \mathcal{E}\mathcal{S}(\mathfrak{M}^\Pi_G)$:

$$r_M: (\mathfrak{A}^\Pi)^{**} \to (\mathfrak{M}^\Pi_G)^*$$ is the natural restriction

and

$$\omega(x) = \int_{\mathcal{M}^\Pi} \omega_m(x) \mu_\omega(dm) \text{ for any } x \in (\mathfrak{A}^\Pi)^{**} \supseteq \mathfrak{A}^\Pi. \quad (5.1.146)$$

Proof. (i) is clear from the definition of $p_M$, compare also [53, 4.1.36]. (ii) is a rephrasing of (5.1.138). Since $\delta_F$ corresponds to a pure state on $\mathcal{M}^G$ and $p_M$ is affine, $\mathcal{S}_F$ is a face. Closedness of $\mathcal{S}_F$ follows from the continuity of $p_M$, and convexity is clear. The rest of (iii) is contained in the concluding remark of 5.1.36 which implies also the first statement of (iv). A proof of the second statement of (iv) is an easy adaptation of that of 5.1.17 for the case of factor states. It remains to prove (v):

Let $\tilde{\omega} \in \mathcal{S}_v((\mathfrak{A}^\Pi)^{**})$ be the unique normal extension of $\omega \in \mathcal{S}(\mathfrak{A}^\Pi)$ and $(\pi_\omega, \mathcal{H}_\omega, \Omega_\omega)$ be the corresponding cyclic representation of $(\mathfrak{A}^\Pi)^{**}$. Denote by $\hat{\mu}_\omega$ the orthogonal measure (cf. [53, 4.1.20]) on $\mathcal{S}(\mathfrak{A}^\Pi)^{**}$ corresponding to the canonical decomposition of $\tilde{\omega}$ with respect to the subalgebra $\pi_\omega(\mathfrak{M}^\Pi_G)$ of the center of $\pi_\omega((\mathfrak{A}^\Pi)^{**})$, compare [53, 4.1.25]:

$$\tilde{\omega}(x) = \int \varphi(x) \hat{\mu}_\omega(d\varphi), \text{ for all } x \in (\mathfrak{A}^\Pi)^{**}. \quad (5.1.147)$$

The mapping

$$y(\mathfrak{M}^\Pi_G) \mapsto \hat{y}(\mathcal{S}(\mathfrak{A}^\Pi)^{**})), \hat{y}(\varphi) := \varphi(y),$$

restricted to the subalgebra $p_\omega \mathfrak{M}^\Pi_G$ (which is isomorphic to $\pi_\omega(\mathfrak{M}^\Pi_G)$ for the uniquely determined projector $p_\omega \in \mathfrak{M}^\Pi_G$) provides an isomorphism of the $W^*$-algebras $p_\omega \mathfrak{M}^\Pi_G$ and $L^\infty(\hat{\mu}_\omega)$, [118, Chap. I.9] and [53, 4.1.22]. Hence, for $y_j \in p_\omega \mathfrak{M}^\Pi_G$ ($j = 1, 2$) we have

$$\langle y_1, y_2 \rangle(\varphi) = \hat{y}_1(\varphi) \hat{y}_2(\varphi), \text{ for } \varphi \in \text{supp } \hat{\mu}_\omega. \quad (5.1.148)$$

Clearly, $\varphi(y) = 0$ for $y \in (I - p_\varphi) \mathfrak{M}^\Pi_G$ and $\varphi \in \text{supp } \hat{\mu}_\omega$. This fact together with (5.1.148) implies that the restriction $r_M \varphi$ is a pure state on $\mathfrak{M}^\Pi_G$ for $\varphi \in \text{supp } \hat{\mu}_\omega$, $r_M \varphi := m_\varphi \in \mathcal{M}^\Pi$. The $w^*$-topology of the state space is Hausdorff and the clopen sets form a basis of the topology of $\mathcal{M}^\Pi$. This and the isomorphism of $L^\infty(\hat{\mu}_\omega)$ with $p_\omega \mathfrak{M}^\Pi_G$ imply that the restriction of the mapping $r_M$ onto $\text{supp } \hat{\mu}_\omega$ is a bijection onto

$$\text{supp } p_\omega := \{ m \in \mathcal{M}^\Pi : m(p_\omega) = 1 \}. \quad (5.1.149)$$

Denote $\omega_m := \varphi$ iff $r_M \varphi = m \in \mathcal{M}^\Pi$. Let $\mu_\omega$ be the image of $\hat{\mu}_\omega$ under $r_M$:

$$\mu_\omega := \hat{\mu}_\omega \circ r_M^{-1}$$ is a regular Borel measure on $\mathcal{M}^\Pi$. \quad (5.1.150)
Since $p_M \omega = r_M \tilde{\omega}$, $\mu_\omega$ is the measure specified in (v). The measurability of the function $\tilde{\omega} : m \mapsto \omega_m$ defined on $\text{supp } p_\omega = \text{supp } \mu_\omega$ is clear, compare [53, 4.1.36]. The integral in (5.1.146) is then another form of (5.1.147). This concludes the proof. 

5.1.39 Note. Let $r_\Theta : S((A^\Pi)^{**}) \rightarrow S(A^\Pi)$ be the restriction mapping. Let $e_* : S(A^\Pi) \rightarrow S_*(A^\Pi)^{**}$ be the normal extension, $e_* \omega = \tilde{\omega}$. Then $p_M = r_M \circ e_*$. For a general $\varphi \in S((A^\Pi)^{**})$, it is

$$r_M \varphi \neq (p_M \circ r_\Theta) \varphi. \quad (5.1.151)$$

Since $\omega_m \in \text{supp } \mu_\omega$ need not be normal, the inequality (5.1.151) holds also for $\varphi = \omega_m$ in general. The open question is, however, whether (under some conditions) $(p_M \circ r_\Theta) \omega_m \in \mathcal{M}^\Pi = \mathcal{E} S(A^\Pi_G)$ or, at least, when the canonical measure corresponding to $(p_M \circ r_\Theta) \omega_m \in S(C(\mathcal{M}^\Pi))$ is concentrated on a set $F_\Theta^{-1}(F)$ for some $F \in \mathcal{M}^G$, where

$$F_\Theta : \mathcal{M}^\Pi \rightarrow \hat{\mathcal{M}}^G$$

is the natural mapping defined according to (5.1.87) $\land$ (5.1.93), and $\hat{\mathcal{M}}^G$ is the one-point compactification of $\mathcal{M}^G$. Let us write down the definition of $F_\Theta$ explicitly (see also proof of 5.1.19):

(*)  Let $E^\Pi$ be the projection-valued measure defined on Borel subsets of $\mathfrak{g}^*$ with values in $\mathcal{Z}$, as determined in 5.1.29 and in 5.1.33. Let $\hat{\mathfrak{g}}^* := \mathfrak{g}^* \cup \{ \infty \}$ be the one-point compactification of $\mathfrak{g}^*$ and $\hat{\mathcal{M}}^G := \hat{\mathfrak{g}}^* \cup \{ m_0 \}$, where $m_0$ is an isolated point. Let $\mathcal{M}^\Pi := \mathcal{E} S(A^\Pi_G)$ be the spectrum space of the algebra $\mathfrak{M}^\Pi_G = C(\mathcal{M}^\Pi)$ generated by projectors $E^\Pi_{\Theta}(B)$ (Borel $B \subset \mathfrak{g}^*$), i.e. by continuous functions $m \mapsto m(E^\Pi_{\Theta}(B))$, $m \in \mathcal{Z} := \mathcal{E} S(\mathfrak{Z})$. Define the (continuous) mapping $F_\Theta : \mathcal{M}^\Pi \rightarrow \hat{\mathcal{M}}^G$ by

(i)  $F_\Theta(m) \in \mathfrak{g}^*$ iff there is a bounded Borel $B \subset \mathfrak{g}^*$ such that

$$\omega_m(E^\Pi_{\Theta}(B)) \equiv m(E^\Pi_{\Theta}(B)) = 1, \quad (5.1.152)$$

and, in this case, $F_\Theta(m)(\xi) := m(X_{\Theta} E^\Pi_{\Theta}(B))$ for all $\xi \in \mathfrak{g}$. Here $X_{\Theta}$ are defined in 5.1.29. The character property of $m$ ensures independency of $F_\Theta(m)$ on $B$ satisfying (5.1.152).

(ii)  $F_\Theta(m) := m_0$ iff $m(I - p_G) = 1$, i.e. iff $m = m_0 \in \mathcal{M}^\Pi$, 5.1.32.

(iii)  $F_\Theta(m) := (\infty)$ iff $m(I - p_G) = 0$ and (5.1.152) is false for all bounded Borel subsets $B \subset \mathfrak{g}^*$: $m(E^\Pi_{\Theta}(B)) = 0$.

The same definition applied to all $m \in \mathcal{Z}$ leads to the mapping

$$F_\Theta \circ r_M : \mathcal{Z} \rightarrow \hat{\mathcal{M}}^G, \quad \mathcal{Z} := C(\mathcal{Z}), \quad \text{(5.1.153)}$$

which is continuous on the whole $\mathcal{Z}$. 
The mapping $F_\theta \circ r_M$ determines the projectors $E_\theta^\Pi(B)$. For bounded $B$ we have ($\overline{B} := \text{closure, } B^* := \text{interior}^5$)

$$m(E_\theta^\Pi(\overline{B})) = 1 \text{ iff } m \in ([F_\theta \circ r_M]^{-1}(\overline{B}))^0 = ([F_\theta \circ r_M]^{-1}(\overline{B}))^0.$$ (5.1.154)

If we extend the Ad$^*$(G) to the whole $\mathcal{M}^G$ by the requirement of Ad$^*(G)$-invariance of the points $m_o$ and $(\infty)$ we see, that $F_\theta$ is $G$-equivariant:

$$F_\theta(\sigma_g^* m) = Ad^*(g) F_\theta (m), \text{ for all } m \in \mathcal{M}^\Pi, \ g \in G.$$  (5.1.155)

5.1.40. The projection measure $E_\theta^\Pi$ on $\mathfrak{g}^*$ together with the Ad$^*$-action of $G$ determine a macroscopic limit of the system $(\mathfrak{A}^\Pi, \sigma_G)$. This formulation together with the mapping $p_M$ of $\mathcal{S}(\mathfrak{A}^\Pi)$ into the classical macroscopic states of the system will enable us to generalize the notion of the macroscopic limit to much more general situations. We shall investigate also the dynamics of the system $(\mathfrak{A}^\Pi, \sigma_G)$ (resp. of its generalizations) if the time evolution were not included in the action $\sigma_G$ as the action of a one parameter subgroup of $G$. The action $\sigma_G$ of the ‘kinematical group’ $G$ allows us, as we shall show, to introduce rather wide class of ‘mean-field-type’ time evolutions connected with noncompact groups $G$ - at least for a large $\sigma_G$-invariant subset of states in $\mathcal{S}(\mathfrak{A}^\Pi)$. Also automorphic time evolutions $\tau : t \mapsto \tau_t \in ^*\text{-Aut} \mathfrak{A}$ of a system $(\mathfrak{A}, \sigma_G, \tau_\mathfrak{A})$ will be considered.

5.2 Generalized macroscopic limits

5.2.1. We have considered, in the preceding section, a macroscopic limit of the system $(\mathfrak{A}^\Pi, \sigma_G)$. This system was of a rather special type: the algebra $\mathfrak{A}^\Pi$ was the infinite tensor product of identical copies $\mathfrak{A}_j$ ($j \in \mathbb{Z}_+ =: \Pi$) of a $C^*$-algebra $\mathfrak{A}_0$ and the automorphism group $\sigma_G$ left each of the copies $\mathfrak{A}_j$ invariant: $\sigma_g x \in \mathfrak{A}_j$ for each $x \in \mathfrak{A}_j$, for all $g \in G$ and any $j \in \mathbb{Z}_+ \equiv \Pi$. We shall now generalize the procedure of obtaining a macroscopic limit to much more general situations. We shall ignore here possible quasilocal structures of the considered $C^*$-algebra $\mathfrak{A}$; the usage of the term ‘macroscopic limit’ can be here understood in an analogy with the preceding section.

The notion of the macroscopic limit introduced in this section is nonunique. A certain arbitrariness is contained, however, also in the corresponding notion of Sec.5.1: The generators $X_\xi^N$ of the restriction of $\sigma_G$ to $\mathfrak{A}_j := \otimes_{j=1}^N \mathfrak{A}_j \subset \mathfrak{A}^\Pi$ are determined up to additive constants $a_N(\xi)$, $a_N \in \mathfrak{g}^*$, $\xi \in \mathfrak{g}$, hence also the choice of $\mathfrak{A}_G \subset \mathfrak{Z}$ was arbitrary in a certain sense. We shall avoid partly this kind of ambiguity in this section: we are dealing here just with the action of $\sigma_G$, and not with generators.

5.2.2. Let $G$ be a connected Lie group, $\mathfrak{g}$ its Lie algebra, and $\mathfrak{g}^*$ the dual of $\mathfrak{g}$. Let $\mathfrak{A}$ be an arbitrary $C^*$-algebra, $\mathfrak{A}^{**}$ its double dual $W^*$-algebra, and $\mathfrak{Z}$ is the center of $\mathfrak{A}^{**}$. The algebra

\footnotesize
\begin{itemize}
  \item[5] The relation (5.1.154) has been proved in the assumption that any projector $p \in \mathfrak{M}_G^\Pi$ is of the form $p = E_\theta^\Pi(B)$ for some $B \subset \mathfrak{g}^*$, if $p(I - p_G) = 0$.
  \item[5] $a_N$ forms a zero-dimensional orbit of $Ad^*(G) : a_N([\xi, \eta]) \equiv 0$.
\end{itemize}

\normalsize
\( \mathfrak{A} \) is naturally contained in \( \mathfrak{A}^{**} \) as a \( \sigma(\mathfrak{A}^{**}, \mathfrak{A}^*) \)-dense \( C^* \)-subalgebra. Any state \( \omega \in \mathcal{S}(\mathfrak{A}) := \) the state space of \( \mathfrak{A} \), has a **natural extension**

\[ e_\omega \omega \in \mathcal{S}_e(\mathfrak{A}^{**}) := \text{the normal states of } \mathfrak{A}^{**}. \]

If \( \mathfrak{M} \) is a \( C^* \)-subalgebra of \( \mathfrak{A}^{**} \), then \( r_{\mathfrak{M}} : \mathcal{S}(\mathfrak{A}^{**}) \to \mathcal{S}(\mathfrak{M}) \) is the **restriction mapping**; \( r_{\mathfrak{M}} \) is \( \sigma(\mathfrak{A}^{**}, \mathfrak{A}^{**}) = \sigma(\mathfrak{M}, \mathfrak{M}) \) continuous and maps normal states onto normal states.

**Let** \( \sigma : G \to *-\text{Aut} \mathfrak{A}, \ g \mapsto \sigma_g \) **be a given action of** \( G \); by the same symbol \( \sigma_G \) is denoted the canonical extension of \( \sigma_G \subset *-\text{Aut} \mathfrak{A} \) to the action on \( \mathfrak{A}^{**} \) - the double transpose of \( \sigma_G \). This system will be denoted by \( (\mathfrak{A}; \sigma_G) \). \( Z \) **will denote the spectrum space of** \( Z = C(\mathcal{Z}) \).

Let \( g^* \) be endowed with the structure of a Poisson manifold, 5.1.37, given by a **tensor field** \( \lambda \), usually \( \lambda_F(\cdot, \cdot) := -F([\cdot, \cdot]) - \theta_F(\cdot, \cdot) \), i.e.

\[ \{f, g\}(F) := -F([dF_f, dF_g]) - \theta_F(dF_f, dF_g), \ F \in g^*, \ \theta_F \equiv \theta, \quad (5.2.1) \]

where \( f, g \in C^\infty(g^*, \mathbb{R}) \) and \( \theta \) **is a two form on** \( g \) **satisfying**

\[ \theta(\xi_1, [\xi_2, \xi_3]) + \theta(\xi_2, [\xi_3, \xi_1]) + \theta(\xi_3, [\xi_1, \xi_2]) = 0, \quad (5.2.2) \]

for all \( \xi_j \in g, \ j = 1, 2, 3 \). We assume that an action of \( G \) on \( g^* \) is \( \varphi : g \mapsto \varphi_g \), where \( \varphi_G \) is a ‘maximal’ group of Poisson morphisms, i.e. \( \varphi_{gh} = \varphi_g \circ \varphi_h \) \( (g, h, \in G) \), \( \varphi_e := \text{id}_{g^*} \) \( (e := \) the identity of \( G) \); each \( \varphi_e \) is a diffeomorphism of \( g^* \) conserving the **Poisson structure**:

\[ \varphi_h^*\{f, g\} = \{\varphi_h^*f, \varphi_h^*g\}, \ f, g \in C^\infty(g^*, \mathbb{R}), \ h \in G, \quad (5.2.3) \]

and \( \varphi_GF \) \( (\forall F \in g^*) \) are the maximal integral submanifolds of \( \lambda \), [212, Def.3.1&Thm.3.4]. Usually, one takes

\[ \varphi_hF := \text{Ad}^*(h)(F) + a_\theta(h), \ h \in G, \ F \in g^*, \quad (5.2.4) \]

where \( a_\theta \) **is a unique differentiable mapping** from \( G \) to \( g^* \) with the properties, [212]:

(i) \( a_\theta(gh) = \text{Ad}^*(g)(a_\theta(h)) + a_\theta(g), \ \forall g, h, \in G, \]

(ii) \( T_ea_\theta(\xi)(\eta) = \theta(\xi, \eta), \ \forall \xi, \eta \in g, \) where \( T_ea_\theta : g \to g^* \) is the tangent map of \( a_\theta \) at \( e \in G \).

The system \( (\mathfrak{A}; \sigma_G) \) represents a quantal system and \( (g^*, \lambda; \varphi_G) \) is a (generalized) **classical system** which will play the role of a macroscopic limit of the system \( (\mathfrak{A}; \sigma_G) \). Let us introduce candidates for this micro-macro connection:

**5.2.3 Definitions.** Let \( B(g^*) \) be the set of all complex-valued uniformly bounded Borel functions on \( g^* \) and let \( \Sigma_G \) be the Borel \( \sigma \)-algebra of subsets of \( g^* \). Let the **G-measure** \( E \) (of the system \( (g^*, \lambda; \varphi_G) \), resp. of \( (\mathfrak{A}; \sigma_G) \)) be any projection-valued measure on \( g^* \) with values in \( \mathfrak{Z} \), which is \( G \)-equivariant, i.e.

\[ E : \Sigma_G \to \mathfrak{Z}, \ B \mapsto E(B) = E(B)^* = E(B)^2 \in \mathfrak{Z} \quad (B \in \Sigma_G), \quad (5.2.5a) \]
We shall assume in the following that $G$ is the limit of the dimension of any other $(\mathbf{g}^*, \lambda; \phi_G)$.

\[ E(\varphi B) = \sigma_g E(B), \quad \text{for all } B \in \Sigma_G, \text{ and for all } g \in G. \]  

(5.2.5c)

Denote by $E(f) \in \mathfrak{F}$ the integral of $f \in \mathcal{B}(\mathfrak{g}^*)$ over $E$.

Let $p_E := E(g^*)$, $I :=$ the unit of $\mathfrak{A}^*$.

Denote by $\mathfrak{M}(E)$ the $W^*$-subalgebra of $\mathfrak{F}$ generated by $E(f)$, $f \in \mathcal{B}(\mathfrak{g}^*)$.

Let $\mathfrak{B}(E)$ denote the Borel*-algebra \[ [235, 4.5.5] \text{ in } \mathfrak{F} \text{ generated by all the } E(f), f \in \mathcal{B}(\mathfrak{g}^*); \]

this means that $\mathfrak{B}(E)$ is the smallest $C^*$-subalgebra of $\mathfrak{F}$ containing all the $E(B)$ ($B \in \Sigma_G$) and with each monotone (increasing or decreasing) sequence $x_i \in \mathfrak{B}(E)$, it is also $\text{s}-\text{lim } x_j \in \mathfrak{B}(E)$. Clearly $\mathfrak{B}(E) \subset \mathfrak{M}(E)$. Here $\mathfrak{M}_s$ is the set of all selfadjoint elements of a $C^*$-algebra $\mathfrak{M}$. The projector $p_E$ is the common unit of $\mathfrak{B}(E)$ and $\mathfrak{M}(E)$. Any projector $q \in \mathfrak{B}(E)$ is of the form $q = E(B)$ for some $B \in \Sigma_G$, what need not be the case for $\mathfrak{M}(E)$. Projections in $\mathfrak{M}(E)$ separate various kinds of spectra of $E$ (resp. of operators $E(f)$ etc.) what need not be the case of $\mathfrak{B}(E)$.

Let supp $E \subset \mathfrak{g}^*$ be the minimal closed $B = \overline{E} \in \Sigma_G$ such that $E(B) = p_E$. Then on the other hand, supp $E(B) := \{ m \in \mathcal{Z} = \mathcal{E}S(\mathfrak{F}) : m(E(B)) = 1 \}$ is a clopen subset of $\mathcal{Z}$. Let

\[ \dim(F) := \text{dimension of the orbit } \varphi_G F \subset \mathfrak{g}^*, \quad \dim(E) = 2k \leq \dim \mathfrak{g}^*, \]

and $\dim(E) := \max\{ \dim(F) : F \in \text{supp } E \}$. The $G$-measure $E$ is trivial iff $\dim(E) = 0$.

The quantal system $(\mathfrak{A}; \sigma_G)$ has a nontrivial macroscopic limit in the classical system $(\mathfrak{g}^*, \lambda; \varphi_G)$ iff there is $E$ such that $\dim(E) \geq 2$. If there is an $E$ such that $\dim(E) = n_G$, and for any other $G$-measure $E'$ it is $\dim(E') \leq n_G$, we say that the system $(\mathfrak{A}; \sigma_G)$ has $G$-macroscopic limit of the dimension $n_G$ (in the classical system $(\mathfrak{g}^*, \lambda; \varphi_G)$). The number $n_G = 2k_G$ is the $G$-macroscopic dimension of $(\mathfrak{A}; \sigma_G)$ and $k_G$ is the $G$-macroscopic number of degrees of freedom of the quantal system $(\mathfrak{A}; \sigma_G)$.

5.2.4. We shall assume in the following that $n_G \geq 2$ and we shall consider only $G$-measures $E$ with $\dim(E) = n_G$. The projectors $p_E$ are, clearly, $G$-invariant:

\[ \sigma_g(p_E) = p_E \quad \text{for all } g \in G \text{ and all } G\text{-measures } E. \]  

(5.2.6)

Let $q \leq p_E$ be another $G$-invariant projector in $\mathfrak{F}$. Then we can define the restriction of $E$ to $q$, the $G$-measure $qE$, by

\[ qE : \Sigma_G \rightarrow \mathfrak{F}, \quad B \mapsto qE(B); \quad p_{qE} = qp_E. \]  

(5.2.7)

If $p_E p_{E'} = 0$ for two $G$-measures $E$ and $E'$ then the mapping

\[ E + E' : B \mapsto E(B) + E'(B) \quad (\forall B \in \Sigma_G) \]  

(5.2.8)
is a $G$-measure with $\dim(E + E') = \max\{\dim(E), \dim(E')\}$, and $p_{E+E'} = p_E + p_{E'}$. For any two $G$-measures $E$ and $E'$, there is a $G$-measure $EsE'$ given by

$$E s E'(B) := E(B) + (I - p_E)E'(B) \quad \forall B \in \Sigma_G.$$  \hfill (5.2.9)

For the support projector $p_{EsE'}$ of the $G$-measure $EsE'$ we have

$$p_{EsE'} = p_E + p_{E'} - p_E p_{E'} = p_E s E,$$  \hfill (5.2.10)

although, in general, $EsE'$ is different from $E'sE$. Now, one has $\dim(EsE') \geq \dim(E)$. Since $p_{EsE'} = p_E \lor p_{E'} := \text{l.u.b.}[p_E; p_{E'}]$, we can endow the set of classes $[E]$

$$[E] := \{E' : p_{E'} = p_E\}$$  \hfill (5.2.11)

with a partial ordering:

$$[E] \succ [E'] \iff p_E \geq p_{E'}.$$  \hfill (5.2.12)

This ordering makes the set $\{[E]\}$ of classes of $G$-measures a directed set.

The same ordering will be considered for any set of subclasses $[E]' \subset [E]$ determined by some further condition $C$, i.e. for classes

$$[E]' := \{E' : p_{E'} = p_E, C(E')\}.$$  \hfill (5.2.13)

Here $C(E')$ means "the $G$-measure $E'$ satisfies the condition $C"$, e.g. $C(E') := (\dim(E') = \dim(E_o))$, or $C(E) := (E(F) \neq 0 \Rightarrow \dim(F) \neq 0)$, etc. The classes (5.2.13) could also be denoted by $[E]$.

5.2.5 Lemma. The function $\dim : g^* \to \mathbb{R}, F \mapsto \dim(F)$ is lower semicontinuous. Hence, the sets $\{F \in g^* : \dim(F) \geq n\}$ are open and the sets $\{F \in g^* : \dim(F) \leq n\}$ are closed in $g^*$ for any $n \in \mathbb{Z}_+$. Specifically, the set $\{F \in g^* : \dim(F) = 0\}$ is closed, and the set $\{F \in g^* : \dim(F) = n\}$ is Borel.

Proof. It was assumed in 5.2.2 that the action $\varphi_G$ is a 'maximal' Poisson action, i.e. the orbits of $\varphi_G$ coincide with the maximal integral manifolds of the Poisson structure $\lambda$ on $g^*$, [212]. The dimension $\dim(F)$ of $\varphi_G F$ is then given by the rank of the skew-symmetric 2-tensor $\lambda_F$ (:= the value of $\lambda$ in the point $F \in g^*$), i.e. by the rank of the mapping $\lambda_F : T_F g^* \to T_F g^*, v \mapsto \lambda_F(v, \cdot)$, denoted by $\text{rank}(\lambda_F)$. Since $\lambda$ depends smoothly on $F$, the function $F \mapsto \dim(F) = \text{rank}(\lambda_F)$ is lower semicontinuous. The remaining assertions then follow.

5.2.6. Let $S_n := \{F \in g^* : \dim(F) \leq n - 1\}, 1 \leq n \leq \dim G$. For such a $G$-measure $E$ with $p_E \neq E(S_n)$ let $r_n E := (p_E - E(S_n))E$, see (5.2.7). Clearly, $\dim(E) = \dim(r_n E)$, if $r_n E \neq 0$. $E$ is a purely nontrivial $G$-measure, if $0 \neq p_E$ and $r_1 E = E$. If $0 \neq E = r_n E$ and $r_{n+1} E = 0$, $E$ is called a purely n-dimensional $G$-measure. For $n := \dim(E)$ the measure $r_n E$ is purely n-dimensional. The G-measures $E + E', EsE'$ and $qE$ (with a $G$-invariant projector $q = qp_E \neq 0$) are purely n-dimensional together with $E$ and $E'$. Let the ordering (5.2.12) be given for the
set of classes \([E] := \{E' : p'_E = p_E \text{ and } E' = r_n E', r_{n+1} E' = 0\}\). In any linearly ordered subnet of such \([E]\)'s there is a natural mapping

\[
\pi_{EE'} : [E'] \to [E], \quad E' \mapsto \pi_{EE'}(E') := p_E E' \in [E] \text{ for } p_{E'} \geq p_E. \tag{5.2.14}
\]

The mappings \(\pi_{EE'}\) define a projective system \([73, \text{Definition 20.1}]\) on the linearly ordered subset \(J\) of classes \([E] : \pi_{EE''} = \pi_{EE'} \circ \pi_{E'E''}\) for \(p_{E''} \geq p_{E'} \geq p_E\) and \(\pi_{EE} = \text{id}_{[E]}\). If \(p \leq p_{E'}\), and \(E := p E'\), then \(E' = E s E'\). We want to show that \(J\) has an upper bound in the set of classes \([E]\) of purely \(n\)-dimensional \(G\)-measures \(E\). This would imply, by the Zorn’s lemma, the existence of the maximal element in the set (uniqueness of the maximal element follows from the directedness of the set).

**5.2.7 Lemma.** Let \(L\) be a set of \(G\)-measures linearly ordered by \(E \leq E' \iff E' = E s E'\). Then \(L\) has an upper bound.

**Proof.** For any \(0 \leq f \in \mathcal{B}(g^*)\) and \(E' \geq E\) it is \(E'(f) \geq E(f)\). Denote

\[
E_L(f) := \text{l.u.b.}\{E(f) : E \in L\} = s\text{-lim}\{E(f) : E \in L\}. \tag{5.2.15}
\]

The mapping \(E_L\) can be extended by linearity to \(\mathcal{B}(g^*)\):

\[
E_L : \mathcal{B}(g^*) \to \mathfrak{3}, \quad f \mapsto E_L(f); \tag{5.2.16}
\]

it is bounded: \(\|E_L(f)\| \leq \|f\| := \sup\{|f(F)| : F \in g^*\}\). Due to continuity of the product in the strong topology, the mapping \(E_L\) is a \(C^*\)-homomorphism of the commutative \(C^*\)-algebra \(\mathcal{B}(g^*)\) into \(\mathfrak{3}\). This implies the \(\sigma\)-additivity of the set-function \(E_L : B \mapsto E_L(B), B \in \Sigma_G\), hence, \(E_L\) is a projection measure. Since \(\sigma_g \in \text{*}-\text{Aut } \mathfrak{3}\), and any automorphism of a \(W^\ast\)-algebra is \(\sigma\)-\(\sigma\)-continuous, \(E_L\) is a \(G\)-measure. Clearly \(E_L \geq E, \forall E \in L\). \(\Box\)

**5.2.8 Proposition.** The directed set of classes of purely \(n\)-dimensional \(G\)-measures has a maximal element.\(^7\)

**Proof.** Let \(J\) be any linearly ordered subset of the directed set; cf. (5.2.12). We shall prove that it is possible to choose \(E \in [E]\) in any \([E] \in J\) in such a way that \([E] \prec [E']\) iff \(E' = E s E'\). Then the result will follow from the Lemma 5.2.7 and from the Zorn lemma. It is clear that the choice \(E \in [E]\) of the desired kind can be made in any finite subset \(K_0 \subset J, [E] \in K_0\).

The desired choice (it will be called a ’consistent choice’) can be made in the subset \(K_E := \{[E'] \in J : [E'] \prec [E]\}\) of \(J\) by \(E' := p_{E'} E\) for any \([E] \in J\), with any fixed \(E \in [E]\). We have to prove existence of a consistent choice on the whole \(J\). Let \(J_0\) be a well ordered cofinal subset of \(J\) (the well ordering of \(J_0\) is that one induced by the ordering of \(J\) - it is possible by the axiom of choice, and cofinality means that for any \([E] \in J\) there is an \([E_j] \in J_0 : [E] \prec [E_j]\)). Now we can choose \(E_j \in [E_j]\) (for all \([E_j] \in J_0\)) in a consistent way: For the successor \([E_{j+1}]\) of \([E_j]\) in \(J_0\) we shall choose \(E_{j+1} := E_j s E_{j+1}'\) with any \(E_{j+1}' \in [E_{j+1}]\), if \([E_j]\) has been defined

\(^7\)The present author was informed about some important set-theoretical concepts connected with this Proposition by the late colleague Ivan Korec (1943 - 1998).
before. If \([E_j]\) is not a successor in \(J_o\), put \(E_j^o := 1.\text{ub.}\{E_k : [E_j] \supset [E_k] \in J_o\); all \(E_k(\in [E_k])\) are mutually consistent\), according to the Lemma 5.2.7, and choose \(E_j := E_j^o sE_j'\) with any \(E_j' \in [E_j]\). Then we can ‘to fill gaps’ by setting \(E := p_E E_j\) for all \([E] < [E_j] \in J_o\). This provides a consistent choice \(E \in [E]\) for all \([E] \in J\), if \(J_o\) is considered as an initial segment of the set of all ordinals. 

**Note:** The same proof applies to purely n-dimensional measures \(E\) of the form \(E = qE\) for any fixed \(G\)-invariant projector \(q \in \mathfrak{z}\).

**5.2.9.** Let \([E]_G^c\) be the maximal element of classes of purely \(n_G\)-dimensional \(G\)-measures and let \(p_G^c : p_E\) for \(E \in [E]_G^c\). Let \([E]_G^k\) be the maximal element of classes of purely \((n_G - 2k)\)-dimensional \(G\)-measures of the form \(E = (I - \sum_{j=0}^{k-1} p_G^j) E\), and for \(E \in [E]_G^c\) let \(p_G^k := p_E, k = 1, 2, \ldots, \frac{n_G}{2}\). Define now the class \([E]_G\) of maximal \(G\)-measures by

\[
[E]_G := \sum_{k=0}^{\frac{n_G}{2}} [E]_G^k, \text{ with } E \in [E]_G \text{ iff } E = \sum_{k=0}^{\frac{n_G}{2}} E_k, \ E_k \in [E]_G^k,
\]

and the sum of mutually orthogonal \(G\)-measures is defined in (5.2.8). The choice of measures \(E \in [E]_G\) for the realization of macroscopic limits corresponds to a requirement of 'maximal sensitivity' of the corresponding macroscopic description of the system \((\mathfrak{a}; \sigma_G)\).

We shall not proceed further in an analysis of the set \([E]_G\) and we shall not try to specify some 'most convenient' element \(E \in [E]_G\) as a representative of the macroscopic limit. Let us choose any fixed \(E_\theta \in [E]_G\).

**5.2.10 Definitions.** The projection-valued measure \(E_\theta \in [E]_G\) on the Poisson manifold \((\mathfrak{g}^*, \lambda; \varphi_G)\), the \(G\)-action on which is 'maximal' (i.e. orbits \(\varphi_G F\) are maximal symplectic immersed submanifolds of \(\mathfrak{g}^*\) the Poisson bracket on which is given by \(\lambda\), for any \(F \in \mathfrak{g}^*\)), with values in \(\mathfrak{z}\) (: the center of \(\mathfrak{a}^{**}\)) is called the \(G\)-macroscopic limit of the system \((\mathfrak{a}; \sigma_G)\) in the classical system \((\mathfrak{g}^*, \lambda; \varphi_G)\). The projector \(p_G := E_\theta (\mathfrak{g}^*)\) is the support projector of the macroscopic limit. The dimension \(n_G\) will be called also the dimension of \(E_\theta\). The Borel*- (resp. the \(W^*\)-) algebra \([235, 4.5.5]\) generated by \(E_\theta\) (resp. by \(E_\theta\) and \(I \in \mathfrak{z}\)) will be called the \(B^*\)- (resp. \(W^*\)-) macroscopic algebra of \(G\)-definiteness (resp. the \(G\)-macroscopic algebra) of the system \((\mathfrak{a}; \sigma_G)\) and will be denoted (in the \(W^*\)-cases) by \(\mathfrak{m}_G\) (resp. by \(\mathfrak{m}_G\)).

Denote by \(p_M : \mathcal{S}(\mathfrak{a}) \to \mathcal{S}((\mathfrak{m}_G), \omega \mapsto p_M \omega := r_{\mathfrak{m}} \circ e_* (\omega), \) where \(r_{\mathfrak{m}}\) is the restriction of \(\mathcal{S}(\mathfrak{a}^{**})\) to \(\mathcal{S}(\mathfrak{m}_G)\) and \(e_*\) is the natural extension from \(\mathcal{S}(\mathfrak{a})\) to \(\mathcal{S}(\mathfrak{a}^{**})\). Let \(\mu_\theta^\omega\) be the probability measure on \(\mathcal{M}^G := \mathfrak{g}^* \cup \{m_0\}, m_0\) is an isolated point) given by

\[
\mu_\theta^\omega (B) := \omega (E_\theta (B \setminus \{m_0\}) + \omega (I - p_G) \delta_m (B), \text{ any Borel } B \subset \mathcal{M}^G,
\]

compare (5.1.137). Let us introduce the set

\[\mathcal{E}_\theta := \{\omega \in \mathcal{S}(\mathfrak{a}) : e_* (\omega (p_G)) = 1, \ \mu_\theta^\omega (\xi^2) = |\mu_\theta^\omega (\xi)|^2 < \infty, \ \forall \xi \in \mathfrak{g}\},\]

compare (5.1.142), where \(\xi \in \mathfrak{g}\) is considered as a linear function on \(\mathfrak{g}^*\), since \(\mathfrak{g} \subset \mathfrak{g}^{**}\).
We can introduce also unbounded operators $X_\xi := E_g(\xi)$ on the Hilbert space $H_u$ of the universal representation of $\mathfrak{A}$. Then we have

5.2.11 Theorem. The Theorem 5.1.38 as well as its proof are valid also after the omission of the index $\Pi$ everywhere in its formulation and exchange of $\text{Ad}^*(G)$ by $\varphi_G$, with the interpretation of symbols according to 5.2.10.

5.2.12 Note. We could now, after the recognizing of the Theorem, to continue in the choices of $E_g \in [E_g]_G$ according to the following idea: Choose $E_g$ such that the sets $S_F$ of states with sharp values of the macroscopic observables (cf. 5.1.38 (iii)) are in a certain sense 'maximal'. We shall not make this idea precise here. We believe, however, that continuing in this direction we could obtain $E_g$ 'essentially uniquely' - up to natural coordinate transformations in the space $g^*$.

5.2.13 A scheme of 'macroscopic quantization'.

Having once a classical limit in the form of the couple \{$(g^*, \lambda; \varphi_G), (\mathfrak{M}_G; \sigma_G)$\}, where $\sigma_G \subset \text{*-Aut } \mathfrak{M}_G$, we are interested in the question: Can the original algebra $\mathfrak{A}$ be reconstructed from this classical limit? Keeping in mind the model of Sec.5.1 we propose the following scheme for obtaining the algebra $\mathfrak{A}$ of a system $(\mathfrak{A}; \sigma_G)$, the macroscopic limit of which is $(\mathfrak{M}_G; \sigma_G; E_g)$ (here the measure $E_g$ symbolizes the connection with the classical system $(g^*, \lambda; \varphi_G)$), (let us denote by MQ the following scheme):

(MQ) Find a faithful representation $\rho$ of $\mathfrak{M}_G$ in a Hilbert space $\mathcal{H}_\rho$ (necessarily nonseparable) with the properties:

(i) There is a simple $\text{C}^*$-subalgebra $\mathfrak{A}$ of $\mathcal{L}(\mathcal{H}_\rho)$ such that the center of its commutant $\mathfrak{A}'$ contains $\rho(\mathfrak{M}_G)$; $\sigma_G$ extends to an automorphism group of $\mathfrak{A}$.

(ii) $\mathfrak{A}$ is expressible as the norm-closure of union of a net of von Neumann subalgebras $\mathfrak{A}_j (j \in J := \text{a directed set}): j \prec k \Rightarrow \mathfrak{A}_j \subset \mathfrak{A}_k$.

(iii) Each $\mathfrak{A}_j$ is a $\sigma_G$-invariant subset of $\mathfrak{A}$ and the restriction of $\sigma_G$ to any $\mathfrak{A}_j (j \in J)$ is unitarily implementable (i.e. it exists a strongly continuous unitary representation $U^j$ of $G$ in $\mathcal{H}_\rho$ such that $\sigma_g(x) = U^j(g)xU^j(g^{-1})$ for all $x \in \mathfrak{A}_j$, $g \in G$ and $j \in J$).

(iv) Each $\mathfrak{A}_k (k \in J)$ is generated by all $\mathfrak{A}_j$ with $j \prec k$ ($j \neq k$) as well as by the bounded Borel functions of the selfadjoint generators $X_\xi^k (\xi \in g)$ of the one parameter groups $t \mapsto U^k(\exp(t\xi))$.

Hence the proposed ‘quantization procedure’ of the classical system $(g^*, \lambda; \varphi_G)$ consists in finding an ‘imprimitivity system’ $(\mathfrak{M}_G; \sigma_G)$ (cf. [321]) determined by a choice of a $G$–measure $E_g$ (in some commutative $\text{C}^*$-algebra $\mathfrak{M}_G$, where $\sigma_G \subset \text{*-Aut } \mathfrak{M}_G$ is determined by $\sigma_g E_g(B) := E_g(\varphi_g B)$, $g \in G$, $B$ = Borel subsets in $g^*$), and afterwards applying the scheme (MQ) of ‘macroscopic quantization’ to $(\mathfrak{M}_G; \sigma_G)$. We shall not investigate here conditions of existence.
and a ‘degree of uniqueness’ of this recipe. The scheme is nonempty, since it is fulfilled e.g. by the models considered in Sec.5.1 if $U(G)$ is irreducible, 5.1.3.

The question of obtaining a microscopic quantum dynamics of this ‘quantized macroscopic system’ corresponding to its given classical time evolution is posed and solved in the next Chapter 6.
Chapter 6

Mathematical structure of QM mean-field theories

6.1 General considerations

6.1.1. The formalism developed in Chap. 5 will be used in this chapter for a determination of a microscopic time evolution of an infinite quantum system from the macroscopic (classical) evolution. It is clear that such an unusual determination of microscopic dynamics is possible for a very special type of interactions only. We shall show that this is the case of a wide class of quantum mean-field theories, at least in the time invariant subset $S^\Pi_g$ of the set $S(\mathfrak{A}^\Pi)$ of all the microscopic states on the quasilocal algebra $\mathfrak{A}^\Pi$, cf. Sec. 5.1, esp. 5.1.32; cf. also 'classical states' in [155]. The systems of the considered type are determined by the couple $(\mathfrak{A}; \sigma_G)$ consisting of a $C^*$-algebra $\mathfrak{A}$ ($:= \mathfrak{A}^\Pi$, e.g.; the upper indices $\Pi$ will be usually omitted in this chapter) and of a representation $\sigma(G) := \sigma_G \subset \text{\ast-Aut } \mathfrak{A}$, cf. 5.2.2, as well as by a $G$-measure $E_g$, 5.2.3, and by a classical Hamiltonian function $Q \in C^\infty(\mathfrak{g}^*, \mathbb{R})$. A subclass of these systems consists of thermodynamic limits $N \to \infty$ of systems of the total number $N$ of quantal (mutually equal) subsystems with dynamics described by local Hamiltonians $Q^N$. These local Hamiltonians are invariant with respect to any permutations of $N$ subsystems and the $k$-body interaction constants (i.e. coefficients at products of $k$ operators corresponding to different subsystems) are proportional to $N^{1-k}$. We can construct such a sequence of the 'local time evolutions' $\tau^N \subset \ast\text{-Aut } \mathfrak{A}$ in the following way:

Let us keep the notation of Sec. 5.1, and let a basis $\xi_j$ ($j = 1, \ldots n$) of $\mathfrak{g}$ be fixed, the dual basis being $\{f_j : j = 1, 2, \ldots n\} \subset \mathfrak{g}^*$. Let $X_j$ ($j = 1, 2, \ldots n$) be the selfadjoint generators of the one parameter unitary groups $t \mapsto U(\exp(t\xi_j))$ on $\mathcal{H}$, 5.1.3. Let $Q$ be a polynomial in $n$ variables and with a prescribed order of multiplication of variables in such a way that the element $Q(\xi_1, \xi_2, \ldots \xi_n)$ of the Lie algebra envelope has the following property:

---

1For some history, general meaning and technical construction of dynamics (given by full and correctly solved microscopic evolutions - without any approximations) of “Quantum mean-field theories” see also [40], and for some of its applications look in [41].
(SA) Let \( Q \equiv \sum_{k=0}^{n} Q_k \), where \( Q_k \) is a homogeneous polynomial of degree \( k \). In any continuous unitary representation \( U \) of the group \( G \) on a separable Hilbert space \( \mathcal{H} \), the operators \( Q_k(X_1, X_2, \ldots, X_n) \) defined on analytic elements of \( U \) are essentially selfadjoint, for all \( k = 1, 2, \ldots, q \).

This property (SA) is fulfilled e.g. if all the \( Q_k(\xi_1, \xi_2, \ldots, \xi_n) \) are symmetric and elliptic, cf. [13, Chap.11]. Then we define the local Hamiltonians \( Q^N \), with (5.1.14), denoting by \( N \) also an \( N \)-point subset of \( \Pi \):

\[
Q^N := N Q(X_{1N}, X_{2N}, \ldots, X_{nN}), \quad X_{jN} := \frac{1}{N} X_j^N, \quad N = 1, 2, \ldots;
\]

(cf. (5.1.118), i.e.

\[
X_j^N := \sum_{k=1}^{N} \pi_k(X_j), \quad j = 1, 2, \ldots, n, \quad k \in N \subset \Pi,
\]

which can be considered as (essentially) selfadjoint operators on \( \mathcal{H}_{\Pi} (= \mathcal{H}_N \otimes \mathcal{H}_{\Pi\setminus N} \equiv \Pi\text{-tuple tensor product}) \). For any \( x \in \mathfrak{A} \) (\( = \mathfrak{A}_{\Pi} \subset \mathcal{L}(\mathcal{H}_{\Pi}) \) we set

\[
\tau^N_t(x) := \exp(it Q^N) x \exp(-it Q^N), \quad t \in \mathbb{R},
\]

and these mappings \( \tau^N_t \) clearly form a one parameter group of *-automorphisms of \( \mathfrak{A} \) for each finite \( N \). Systems of this type were introduced in [155] for the case of spin systems (i.e. \( \dim \mathcal{H} \) was finite). It was shown in [155, 40] that the sequence \( \{\tau^N : N = 1, 2, \ldots\} \) determines an evolution \( \tau^Q \) of the observables of the form \( X_{\xi\Pi} \), cf. 5.1.7 and 5.1.9, which is expressed in our notation by the formula

\[
\tau^Q_t(X_{\xi\Pi}) := w^*_0 - \lim_{N \to \infty} \tau^N_t(X_{\xi N}) = \int f_{\xi}(\varphi_t^Q F) E_\theta(dF),
\]

where \( w^*_0 \)-topology on a von Neumann algebra containing \( \mathfrak{A} \) and \( X_{\xi\Pi} (\xi \in \mathfrak{g}) \) is determined by the set of the ‘classical states’. The integral in (6.1.3) corresponds to the integral in [155, (2.29)], which, specified to our case, reads:

\[
\lim_{N \to \infty} \omega(\tau^N_t(X_{\xi N})) = \int f_{\xi}(\varphi^Q_t F) \omega(E_\theta(dF)), \quad \omega \in \mathcal{S}_0.
\]

We have used notation \( f_{\xi}(F) := F(\xi) (\xi \in \mathfrak{g}, F \in \mathfrak{g}^*) \), and \( \varphi^Q \) is the classical flow on \( \mathfrak{g}^* \) corresponding to the Hamiltonian function \( Q \in C^\infty(\mathfrak{g}^*, \mathbb{R}) \), \( Q(F) := Q(F_1, F_2, \ldots, F_n) \), with \( F_j := f_{\xi_j}(F) = F(\xi_j), \quad (F \in \mathfrak{g}^*) \); the introduction of the flow \( \varphi^Q \) will be discussed later in this section. The natural question is, however, whether the limits

\[
\tau^Q_t(x) := (\text{some topology}) - \lim_{N \to \infty} \tau^N_t(x)
\]

exist for some \( t > 0 \) and for sufficiently many \( x \in \mathfrak{A} \), so that \( \tau^Q_t \) could be extended to a one parameter group (resp. semigroup) of mappings of \( \mathfrak{A} \) (or of some of its completions) representing in a reasonable manner some time translations. We shall show that this is indeed the case, and
6.1.2. Let \((\mathfrak{g}, \lambda; \varphi_G)\) be a Poisson manifold with the Poisson action \(\varphi_G\) of the Lie group \(G\) the orbits of which coincide with the maximal integral submanifolds of the Poisson structure \(\lambda\), cf.[212], and 5.1.37, and 5.2.2. We shall assume, for simplicity, that \(\varphi_G := \text{Ad}^*(G)\) and \(\lambda_F(dF, dg):= -F([d_F f, d_F g])\) for all \(f, g \in C^\infty(\mathfrak{g}^*, \mathbb{R})\). Let \(Q \in C^\infty(\mathfrak{g}^*, \mathbb{R})\) be such a fixed function on \(\mathfrak{g}^*\), that the corresponding Hamiltonian vector field \(\sigma_Q\) on \(\mathfrak{g}^*\), (5.1.144), is complete. This means that there is a one parameter group \(t \mapsto \varphi^Q_t\) \((\varphi^Q_{t+s} = \varphi^Q_t \circ \varphi^Q_s\) for all \(t, s \in \mathbb{R}\)) of Poisson morphisms of \((\mathfrak{g}^*; \lambda)\) the derivative of which is \(\sigma_Q\). Remember that \(\sigma_Q\) is complete for any \(Q\) in the case of compact groups \(G\), in which case the \(\text{Ad}^*(G)\)-orbits are compact. The tangent spaces \(T_F \mathfrak{g}^*\) \((F \in \mathfrak{g}^*)\) will be identified with the linear manifold \(\mathfrak{g}^*\) in the canonical way. Then we have also the canonical identification \(T^*_F \mathfrak{g}^* = \mathfrak{g}\) of the cotangent spaces in any point \(F \in \mathfrak{g}^*\) with the Lie algebra \(\mathfrak{g}\) of \(G\). Let \(f_\xi \in C^\infty(\mathfrak{g}^*, \mathbb{R})\) (for any \(\xi \in \mathfrak{g}\)) be the linear function

\[
f_\xi : F \mapsto f_\xi(F) := F(\xi)
\]

Any element \(\xi\) of the Lie algebra \(\mathfrak{g}\) determines also a covector field on \(\mathfrak{g}^*:\)

\[
df_\xi : F \mapsto df_\xi = \xi \in \mathfrak{g} = T^*_F \mathfrak{g}^*.
\] (6.1.6)

The Hamiltonian (contravariant) vector field corresponding to the Hamiltonian function \(f_\xi\) coincides with the vector field \(\sigma_\xi\) determined by the flow

\[
\varphi^\xi : (t; F) \mapsto \varphi^\xi_t(F) := \text{Ad}^*(\exp(t\xi))F
\] (6.1.7)
on \(\mathfrak{g}^*\). We have the relations:

\[
\{h, f_\xi\}(F) = -F([dh, df_\xi]) = df_\xi(\sigma_h) = -dFh(\sigma_\xi), \quad h \in C^\infty(\mathfrak{g}^*, \mathbb{R}),
\] (6.1.8)

where \(\sigma_h\) is the Hamiltonian vector field corresponding to the Hamiltonian function \(h\), cf. (5.1.144) and (5.1.145).
6.1.3. Let \( g_Q : \mathbb{R} \times g^* \rightarrow G, \ (t; F) \mapsto g_Q(t, F) \) be a function determining the Hamiltonian flow \( \varphi^Q_t \) with the help of the action \( \varphi_G := Ad^*(G) \) in the following sense:

\[
Ad^*(g_Q(t, F))F = \varphi^Q_t(F) := \varphi^Q_tF, \quad \text{for all } t \in \mathbb{R}, \text{ and for all } F \in g^*.
\] (6.1.9)

Such functions \( g_Q \) exist due to \( \varphi^Q \)-invariance of the maximal integral submanifolds of \( \varphi_G \) (i.e. the orbits of \( Ad^*(G) \)) with respect to any Hamiltonian flow. Let us assume differentiability of \( g_Q \) and set

\[
\beta^Q_F := \left. \frac{d}{dt} \right|_{t=0} g_Q(t, F), \quad \text{for all } F \in g^*.
\] (6.1.10)

A necessary condition for fulfilment of (6.1.9) is the fulfilment of

\[
F([\beta^Q_F, \eta]) = d_F Q(\sigma_\eta) = -\Omega_F(\sigma_Q, \sigma_\eta) = -d_F f_\eta(\sigma_Q), \quad \eta \in g, \ F \in g^*,
\] (6.1.11)

(cf. (6.1.8)), where \( \Omega \) is the standard Kirillov-Kostant symplectic form on \( g^* \), since the following relation is valid:

\[
\left. \frac{d}{dt} \right|_{t=0} Ad^*(g_Q(t, F))F(\eta) = -F([\beta^Q_F, \eta]), \quad \eta \in g, F \in g^*.
\] (6.1.12)

If we require, in addition to (6.1.11), fulfilment of the following 'cocycle identities':

\[
g_Q(s, \varphi^Q_t F)g_Q(t, F) = g_Q(t + s, F), \quad g_Q(0, F) \equiv e,
\] (6.1.13)

for all \( t, s \in \mathbb{R} \) and all \( F \in g^* \) (with \( e := \) the identity of \( G \)), then the condition (6.1.11) will be also sufficient for the validity of (6.1.9). \textbf{Let} \( \beta^o : F \mapsto \beta^o_F \in g \) \textbf{be any differentiable function on} \( g^* \) \textbf{satisfying}

\[
F([\beta^o_F, \eta]) = 0, \quad \text{for all } F \in g^*, \ \eta \in g.
\] (6.1.14)

Elements \( \beta^o_F \in g \) determine one parameter subgroups of the stability groups of \( F \in g^* \) for the coadjoint action \( Ad^*(G) \), cf. Lemma 3.2.4. If a given \( \beta^Q_F \) satisfies (6.1.11), then also the substitution of

\[
\beta^{Q^o}_F := \beta^Q_F + \beta^o_F
\] (6.1.15)

in place of \( \beta^Q_F \) in (6.1.11) will give a valid equality. \textbf{Let} \( \beta^Q_F \) \textbf{be an infinitely differentiable function of} \( F \in g^* \) \textbf{with values in} \( g \) \textbf{satisfying} (6.1.11). The equation (6.1.13) with the condition (6.1.10) can be rewritten in the form of a differential equation on the group manifold \( G \):

\[
\frac{d}{dt} g_Q(t, F) = T_e(R_{g_Q(t, F)}) \beta^Q_F, \quad \forall t \in \mathbb{R}, \ F \in g^*.
\] (6.1.16)

where \( F_t := \varphi^Q_t(F) \), and \( R_G \) is the right action of the group \( G \) on itself: \( R_g(h) := hg, \ (g, h \in G) \); \( T_e \) is the tangent mapping restricted to the tangent space \( T_e G = g \) of the group \( G \) at the identity \( e \in G, \ T_e(f) : T_e G \rightarrow T_{f(e)} G, \)
6.1. GENERAL CONSIDERATIONS

\[ \xi \mapsto T_e(f)\xi := f_\cdot \xi := \left. \frac{d}{dt} \right|_{t=0} f(\exp(t\xi)) \]

for any differentiable function \( f : G \to G \). According to the general theory of ordinary differential equations, there is a unique solution of (6.1.16) with the initial condition \( g_Q(0,F) = e \).

The solution \( g_Q \) depends, however, on the choice of the covector field \( \beta^Q \) which is, according to (6.1.15), nonunique in the general case.

The cocycle \( g_Q \) is, as we shall see later, the basic dynamical object determining fully the microscopic time evolutions in the mean-field theories of the considered type. Various choices of \( \beta^Q \) corresponding to the various possible choices of \( \beta^o \) according to (6.1.15) will lead to the same classical evolution \( \varphi^Q \) of the subalgebra of classical (intensive) quantities of the extended algebra of quantal observables of the infinite system. The time evolutions of local (microscopic) observables corresponding to various choices of \( \beta^o \) in (6.1.15) are, however, mutually different.

We shall see that the thermodynamic limits described in 6.1.1 correspond to the choice

\[ \beta^Q_F := d_F Q, \quad F \in g^* \]  

(6.1.17)

If we write \( Q(F) \) in the terms of coordinate functions \( F_j := F(\xi_j) \) as in 6.1.1, then we have

\[ d_F Q = \sum_{j=1}^n \frac{\partial Q(F)}{\partial F_j} \xi_j \in g. \]  

(6.1.18)

Let the structure constants of \( g \) in the basis \( \{\xi_j\} \) are \( c^j_{kl} \in \mathbb{R} \), i.e.

\[ [\xi_k,\xi_l] = c^j_{kl} \xi_j. \]  

(6.1.19)

Then we have for the Poisson bracket of two classical Hamiltonians \( Q_1 \) and \( Q_2 \) the expression (called also the Berezin bracket):

\[ \{Q_1,Q_2\}(F) := -F([d_F Q_1,d_F Q_2]) = -c^j_{km} \frac{\partial Q_1}{\partial F_k} \frac{\partial Q_2}{\partial F_m} F_j. \]  

(6.1.20)

6.1.4. Let us describe here, in a heuristic manner, the basic idea leading to the definition of the time evolutions \( \tau^Q \) mentioned in 6.1.1 which will be described in Sec.6.3 in details. It will be also shown in Sec.6.3 that the evolutions obtained from the thermodynamic limits in the 'polynomial cases' (mentioned in 6.1.1 and investigated in Sec.6.2) are special cases of the general definition of \( \tau^Q \) based on the following general ideas.

The cocycle \( g_Q \) reproduces an arbitrary classical Hamiltonian evolution on the Poisson manifold \((g^*,\lambda; Ad^*(G))\) (since \( Q \) is an arbitrary Hamiltonian function) via the given (fixed!) action \( Ad^*(G) \), cf. (6.1.9). We have given an action \( \sigma(G) \in ^* \text{ Aut } A \) and also the corresponding dual action \( \sigma^*(G) \) on the set \( S(A) \) of states on \( A \), cf. (5.1.44). We have also a canonical decomposition of an arbitrary state \( \omega \in S(A) \) into the states \( \omega_m \) corresponding to classical phase space points \( m \in M \), namely (5.1.146), resp. the corresponding statement in 5.2.11. For \( \omega \in S_g := p_G S(A) \), the states \( \omega_m \) lying in the support of the corresponding measure \( \tilde{\mu}_\omega \) on \( S(A^*) \) can be indexed by
$F_m \in \mathfrak{g}^*$, where the classical measure on $\mathfrak{g}^*$ corresponding to the state $\omega_m \in \mathcal{E}_g$ is concentrated on the one point set $\{F_m\}$, cf. 5.1.36 and 5.1.39. Hence we can use the family of mappings
\[
t \mapsto \sigma^*(g_Q(t,F_m)), \; t \in \mathbb{R}, \; m \in \mathcal{M}, \tag{6.1.21}
\]
for a definition of time translations of the states $\omega_m$. Such a definition makes sense since the projection measure $E_g := \sigma^*(g_Q(t,F_m))$ is $G$-equivariant, (5.2.5c), what implies that the classical point-measure corresponding to $\sigma^*(g_Q(t,F_m))\omega_m \in \mathcal{E}_g$ is concentrated on $Ad^*(g_Q(t,F_m))F_m = \varphi^Q_t(F_m) \in \mathfrak{g}^*$; hence the cocycle identity (6.1.13) can be used to prove the group property of mappings (6.1.21). A heuristic definition of the time evolution $\tau^Q$ is then given with the help of the decomposition (5.1.146) by the formula:
\[
\omega(\tau^Q_t(x)) := \int_{\mathcal{M}} \sigma^*(g_Q(t,F_m))\omega_m(x) \mu_\omega(dm), \quad \forall t \in \mathbb{R}, \; \omega \in \mathcal{S}_g. \tag{6.1.22}
\]

We shall see in Sec.6.3 that this intuitive construction leads to a rigorously defined group $\tau^Q$ of $^*$-automorphisms of a $C^*$-subalgebra of the $W^*$-algebra $p_G\mathfrak{K}^{**}$ containing the algebra $\mathfrak{K}$ as well as an algebra $\mathfrak{K}^c$ of classical observables in a natural manner. The algebra $\mathfrak{K}^c$ is then $\tau^Q$-invariant: $\tau^Q_{|\mathfrak{K}^c} = \mathfrak{K}^c$, contrary to the algebra $\mathfrak{K}$ (in a general case).

6.1.5 Remark. The general definition of mean-field time evolutions $\tau^Q$ based on the formula (6.1.22) depends on a topology determined by the subset $\mathcal{S}_g := p_G\mathcal{S}(\mathfrak{A})$ of states on $\mathfrak{A}$ (and their canonical normal extensions to $\mathfrak{A}^{**}$), so called 'classical states'. The reason why we cannot use the set of all states $\mathcal{S}(\mathfrak{A})$ for the definition of $\tau^Q$ can be seen from the thermodynamic limits of polynomial interactions described in Sec. 6.2: In the representations of $\mathfrak{A}$ containing the GNS-representations of states $\{\omega : \omega(p_G) \neq 1\}$ as their subrepresentations the thermodynamic limits of the local evolutions $\tau^N$ do not exist for a general $Q$. This fact can be seen from the definition of the projector $p_G$ in (5.1.120) as well as from considerations in Sec.6.2. Although the resulting (algebraic) concept of $\tau^Q$ can be used in certain cases to a definition of time evolution of all states on $\mathfrak{A}$, such a definition scarcely can be considered as a physically correct consequence of the given interaction $Q$. This interaction does not lead to any reasonable (from the point of view of physics) time evolution of states $\omega$ of the infinite system, the central supports $s_\omega$ of which are orthogonal to $p_G : s_\omega p_G = 0$, i.e. $\omega(p_G) = 0$. Since the set $\mathcal{S}_g = p_G\mathcal{S}(\mathfrak{A})$ is $\tau^Q$-invariant (as will be clear later), the time evolution of states $\omega \in (I - p_G)\mathcal{S}(\mathfrak{A})$, where $I$ is the identity of $\mathfrak{A}^{**}$, can be determined arbitrarily with a help of some group $\tau^Q_R \subset ^*\text{-Aut } (I - p_G)\mathfrak{A}^{**}$. The group $\tau^Q_R$ has nothing to do, in a general case, with the evolution $\tau^Q$. For special choices of the function $Q$, however, the evolution $\tau^Q$ can be defined on a larger subalgebra of $\mathfrak{A}^{**}$ than $p_G\mathfrak{A}^{**}$, hence also an evolution of a set of states larger than $\mathcal{S}_g$ can be defined in a natural way, cf. also [40, Sec.II.C]. This can be seen on the following (seemingly trivial) example.

6.1.6 Example. An important class of 'mean-field' evolutions is obtained by choosing $Q := f_\eta \in \mathfrak{g}^{**}, f_\eta(F) := F(\eta), \eta \in \mathfrak{g}$. We have in this case
\[
g_\eta(t,F) = g_\eta(t,F) := \exp(t\eta), \quad \forall F \in \mathfrak{g}^*, \ t \in \mathbb{R}.
\] 

(6.1.23)

The corresponding time evolution is (due to the independence of \(g_\eta\) on \(F \in \mathfrak{g}^*\)):

\[
\tau_t^Q = \tau_t^\eta := \sigma(\exp(-t\eta)) \in \ast-\text{Aut} \mathfrak{A}, \ t \in \mathbb{R}.
\] 

(6.1.24)

This time evolution is ‘representation independent’ (contrary to the general case of an arbitrary \(Q\) and the definition of the evolution of an arbitrary state \(\omega \in \mathcal{S}(\mathfrak{A})\) is straightforward. Equally straightforward is the canonical extension of \(\tau^n\) to the (equally denoted) group \(\tau^\eta \in \ast-\text{Aut} \mathfrak{A}^{**}\).

This evolution (for unbounded \(X_\eta\), especially that one obtained by the extension to \(\mathfrak{A}^{**}\)) is highly discontinuous, however, and some appropriate continuity properties can be found in a restriction to a properly chosen subset of states of \(\mathcal{S}(\mathfrak{A})\) (this ‘properly chosen set of states’ will be possibly larger than \(p_G\mathcal{S}(\mathfrak{A})\)).

The group \(G\) in the cases of this example is a ‘dynamical group’ of the system \((\mathfrak{A}, \sigma(G))\) containing the time-evolution one parameter group as the subgroup \(\{\exp(-t\eta) : t \in \mathbb{R}\} \subset G\).

6.2 Spin systems with polynomial local Hamiltonians \(Q^N\)

6.2.1. Let us consider the system described in Sec. 5.1: The \(C^*\)-algebra of quasilocal observables \(\mathfrak{A}\) is the \(C^*\)-inductive limit of the sequence of the von Neumann algebras \(\mathfrak{A}^N := \mathcal{L}(\mathcal{H}_N), \ \mathfrak{A} := \mathfrak{A}^{**}\). A compact Lie group \(G\) acts on \(\mathfrak{A}\) by the subgroup \(\sigma(G) := \sigma_G\) of \(*\)-automorphisms of \(\mathfrak{A}\) introduced in 5.1.5. It is assumed in this section that the generators \(X_\xi (\xi \in \mathfrak{g})\) of the representation \(U(G)\) in \(\mathcal{H}\) introduced in 5.1.3 are bounded operators. We shall use the notation of the subsections from 5.1.2 to 5.1.28; we shall write \(\Pi\) for the set of all positive integers. It will be convenient for definiteness and for some technical reasons to work in the subrepresentation \(s_G\pi_u\) of the universal representation \(\pi_u\) of the algebra \(\mathfrak{A}\) in the Hilbert space \(\mathcal{H}_u\). The bidual \(\mathfrak{A}^{**}\) is canonically identified with the bicommutant \(\pi_u(\mathfrak{A})''\) of \(\pi_u(\mathfrak{A})\) in \(\mathcal{L}(\mathcal{H}_u)\), and \(s_G \in \mathfrak{B} := \pi_u(\mathfrak{A})'' \cap \pi_u(\mathfrak{A})'' \subset \mathcal{L}(\mathcal{H}_u)\) is defined in 5.1.11. The following considerations could be extended to the larger representation \(p_G\pi_u\), where \(p_G \in \mathfrak{B}\) is introduced in 5.1.29. Hence we shall work in the framework of the von Neumann algebra \(s_G\mathfrak{A}^{**}\) which is isomorphic with the subalgebra \(P_G\mathfrak{B}^\#\) of \(\mathcal{L}(\mathcal{H}_u)\) via the mapping \(p_G\), cf. 5.1.11. The quasilocal algebra \(\mathfrak{A}\) will be identified with its representation \(s_G\pi_u(\mathfrak{A})\) in the Hilbert space \(s_G\mathcal{H}_u\) or, equivalently, with the corresponding \(C^*\)-subalgebra of the abstract \(W^*\)-algebra \(s_G\mathfrak{A}^{**}\). Remember that \(\mathfrak{A}\) is simple, hence any of its nonzero representations as a \(C^*\)-algebra is faithful.

Let us introduce notation for various elements and subsets of \(s_G\mathfrak{A}^{**}\):

6.2.2 Notation. Let us denote:

(i) \(E_\mathfrak{g}\) denotes the projection measure \((G\text{-measure}, 5.2.3)\) on the linear space \(\mathfrak{g}^*\) generated by \(E_\mathfrak{g}(F) (F \in \mathfrak{g}^*)\) from 5.1.13; in the notation of 5.1.16 \(E_\mathfrak{g}(B) = c(B)\) for any subset \(B \equiv \mathcal{B}\) of \(\mathfrak{g}^*\).
(ii) \( E_g(f) := \int f(F) E_g(dF) \) for any complex valued function \( f \in L^1(g^*, \mu^*) \) for all \( \omega \in S_\nu(s_G\mathfrak{A}^{**}) := \) the normal states on \( s_G\mathfrak{A}^{**} \), i.e. the integral \( E_g(f) \) is assumed to converge in the \( w^* \)-sense.

(iii) \( \mathfrak{B}^N_0 := \mathfrak{A}^N \cup \{X_{\xi K} : \xi \in g, K \in \Pi\} \subset s_G\mathfrak{A}^{**} \), if the generators \( X_\xi \in \mathcal{L}(\mathcal{H}) \) are bounded, 5.1.3.

(iv) Let \( \mathfrak{N}^c \) be the \( C^* \)-subalgebra of \( s_G\mathfrak{A}^{**} \) generated by all the elements \( E_g(f) \) with uniformly bounded continuous \( f \in C_b(g^*, \mathbb{C}) \).

(v) \( \mathfrak{C}^N := \) the \( C^* \)-algebra generated by \( \mathfrak{A}^N \) and \( \mathfrak{N}^c \); \( \mathfrak{C}^N \) is isomorphic to the \( C^* \)-tensor product \( \mathfrak{A}^N \otimes \mathfrak{N}^c \), the isomorphism being: \( x \otimes z \mapsto xz \in \mathfrak{C}^N \) (\( x \in \mathfrak{A}^N, z \in \mathfrak{N}^c \)), cf [274, 1.22] and [306, IV.4.7].

(vi) \( \mathfrak{C} \) will denote the \( C^* \)-algebra generated by \( \{\mathfrak{C}^N : N \in \Pi\} \); \( \mathfrak{C} \) is isomorphic to the tensor product \( \mathfrak{A} \otimes \mathfrak{N}^c \), cf. 6.2.13.

6.2.3 Notation. Let \( \{\xi_j : j = 1, 2, \ldots n\} \) be a fixed basis of \( g \). Let

\[
X^N_j := |N| X_{jN} := \sum_{k=1}^{|N|} \pi_k(X(\xi_j)), \quad X(\xi) := X_\xi,
\] (6.2.1)

for any \( N \in \Pi \), be the selfadjoint element of \( \mathfrak{A} \) introduced in 5.1.3 as a selfadjoint operator on \( \mathcal{H}_\Pi \) and identified now with \( s_G\pi_u(X^N_j) \). Let us denote

\[
b := \max\{1 + \|X(\xi_j)\| : j = 1, 2, \ldots n := \text{dim } G\}. \tag{6.2.2}
\]

We shall use the Einstein summation rule for the summation over repeated vector indices in \( g \) and \( g^* \). Let \( c^n_{jk} \) be the structure constants of \( g \) in the given basis:

\[
[\xi_j, \xi_k] = c^n_{jk}\xi_m. \tag{6.2.3}
\]

Then we have from (5.1.1):

\[
[X^K_j, X^K_k] = i c^n_{jk}X^K_m, \quad \text{for all } K \in \Pi. \tag{6.2.4}
\]

Let \( Q \) be a polynomial specified in 6.1.1, hence satisfying the property 6.1.1(SA). Let \( Q \) be written in the form of linear combination of \( p \) monomials of the maximal degree \( q \) with the upper bound \( M \geq 1 \) of the absolute values of the coefficients. Let \( Q^K \) be given by (6.1.1) for all \( K \in \Pi \). Let us introduce the notation:

\[
c := \max\{|c^n_{jk}| : j, k, m = 1, 2, \ldots n\}; \quad a_N := \max(nc; 2|N|b), \quad N \in \Pi; \tag{6.2.5}
\]

\[
b(x) := \max(b; \|x\|), \quad x \in \mathfrak{A}. \quad \tag{6.2.7}
\]

We shall use the standard notation for the multiple commutators:
\[ [y, x]^{(m+1)} := [y, [y, x]^{(m)}], \quad [y, x]^{(0)} := x, \quad [y, x] := yx - xy, \quad (6.2.8) \]
for any \( x, y \in \mathfrak{A}^* \). [We shall use also \( |J| := \text{the number of elements of the set } J \).]

**6.2.4 Lemma.** The following estimate is valid for any \( x \in \mathfrak{B}_0^N \) and for all positive integers \( N, K(\geq N), m \):

\[ \|[Q^K, x]^{(m)}\| \leq \frac{b(x)}{\xi} (m - 1)! (Mpq^2b^{p-1}a_N)^m. \quad (6.2.9) \]

**Proof.** Each multiple commutator in (6.2.9) can be written in the form of a finite linear combination of monomials \( P^{(m)} \) in the variables \( X_{jr} \) and \( y_r \), where \( y_r \in \mathfrak{B}_0^N \) is of one of the forms of the multiple commutators occurring in the two following formulas:

\[ \|[X_{j_1}^N, [X_{j_2}^N, \ldots [X_{j_l}^N, x] \ldots ]]\| \leq (2bN)^r \|x\|, \quad x \in \mathfrak{B}^N; \quad (6.2.10) \]

\[ \|[X_{j_1}^N, [X_{j_2}^N, \ldots [X_{j_r}^N, X_{kL}] \ldots ]]\| \leq (mc)^r b, \quad L \in \Pi. \quad (6.2.11) \]

These estimates of \( \|y_r\| \) are easy consequences of the definitions as well as of the relations (6.2.4). Let \( r \in \mathbb{Z}_+ \) be called the degree of any of the variables denoted by \( y_r \). Then the sum \( \sum r_j \) of degrees of all the variables \( y_{r_j} \) occurring in any of the monomials \( P^{(m)} \) is less or equal to \( m \). The maximal degree of any of the monomials \( P^{(m)} \) is \( m(q - 1) + 1 \), hence we have the estimate:

\[ \|P^{(m)}\| \leq b(x)(a_Nb^{p-1})^m, \quad (6.2.12) \]

where we have used the fact that a variable \( y_r \) of the form given in (6.2.10) occurs in any of the monomials \( P^{(m)} \) at most in the first power (what implies the first power of \( b(x) \) in (6.2.12)), as well as the inequalities \( a_N > b > 1 \) were used in the derivation of (6.2.12).

The maximal value of coefficients at the monomials \( P^{(m)} \) is \( < M^m \). The maximal number of monomials \( P^{(m)} \) occurring in the expression of \( [Q^K, x]^{(m)} \) can be calculated recursively, using the derivation property of the commutators. One has the identity

\[ [x_{j_1} \ldots x_{j_q}, y_{k_1} \ldots y_{k_s}] = \sum_{i=1}^{q} \sum_{j=1}^{s} x_{j_1} \ldots x_{j_{i-1}} y_{k_1} \ldots y_{k_{j-1}} [x_{j_i}, y_{k_j} y_{k_{j+1}} \ldots y_{k_s} x_{j_{i+1}} \ldots x_{j_q}], \quad (6.2.13) \]

in which the commutator of two monomials of degrees \( q \) and \( s \) is expressed as a sum of \( qs \) monomials of degree \( q + s - 1 \) (some of the monomials could be equal to zero). If \( [Q^K, x]^{(m)} \) is a sum of \( n_m \) monomials \( \text{const.} P^{(m)} \) of the maximal degree \( s_m := m(q - 1) + 1 \), then \( [Q^K, x]^{(m+1)} \) is a sum of \( n_{m+1} \) monomials, where

\[ n_{m+1} \leq n_m pqs_m \leq n_m mpq^2. \quad (6.2.14) \]

Since \( n_1 \leq pq \), we obtain the estimate:

\[ n_m \leq \frac{(m - 1)!}{q} (pq^2)^m. \quad (6.2.15) \]
After the multiplication of the right hand side of (6.2.12) by the right hand side of (6.2.15) and by the upper bound $M^m$ of the coefficients at $P^{(m)}$, we obtain the estimate (6.2.9).

6.2.5 Lemma. Let us define

$$\kappa_N := (Mpq^2b^a_N)^{-1}, \text{ for all } N \in \Pi. \quad (6.2.16)$$

Let $|t| \leq \kappa_N$, $x \in \mathcal{B}_0^N$ for a given $N \in \Pi$. Then:

(i) The sums

$$\tau^K_t(x) := e^{itQ^K} x e^{-itQ^K} = \sum_{m=0}^{\infty} \frac{(it)^m}{m!} [Q^K, x]^{(m)}, \quad K \in \Pi, \quad (6.2.17)$$

are convergent in the norm-topology of $\mathfrak{A}$, and this convergence is uniform on $\{K : K \in \Pi\} \times \{t : |t| \leq \kappa_N\} \times \{x : x \in \mathcal{B}_0^N, \|x\| \leq a\}$ for any $a \in \mathbb{R}_+$.

(ii) The following limits exist in $s_G \mathfrak{A}^*$:

$$\tau^K_t(x) := s^* - \lim_{|K| \to \infty} \tau^K_t(x), \quad (6.2.18)$$

where the convergence is understood in the $s^*(s_G \mathfrak{A}^*, s_G \mathfrak{A}^*)$-topology generated by the seminorms $p_\omega$ and $p^*_\omega$ for all $\omega \in \mathcal{S}(s_G \mathfrak{A}^*)$:

$$p_\omega : x \mapsto p_\omega(x) := \sqrt{\omega(xx^*)}, \quad p^*_\omega : x \mapsto p^*_\omega(x) := \sqrt{\omega(x^*x)}. \quad (6.2.19)$$

Proof. The estimates (6.2.9) are independent of $K \in \Pi$ and the corresponding majorizing power series for (6.2.17) is uniformly convergent on the product of the disc $\{t : |t| \leq \kappa_N, t \in \mathbb{C}\}$ and the ball $\{x : x \in \mathcal{B}_0^N, \|x\| \leq a\}$ for any nonnegative $a$. This proves (i). The definition of $s_G$ in 5.1.11 implies the existence of the limits

$$X_{\xi\Pi} := s^* - \lim_{|K| \to \infty} X_{\xi K} = E_0(f_\xi) \in s_G \mathfrak{A}^*, \quad \xi \in \mathfrak{g}, \quad (6.2.20)$$

what implies, in turn, together with the uniform boundedness in $K \in \Pi$ of the multiple commutators in (6.2.17), the existence of the limits

$$s^* - \lim_{|K| \to \infty} [Q^K, x]^{(m)} \in s_G \mathfrak{A}^*. \quad (6.2.21)$$

The statement (i) together with these facts imply (ii).

6.2.6 Lemma. Let $\mathcal{B}^N$ be the $C^*$-subalgebra of $\mathfrak{A}$ generated by $\mathcal{B}_0^N$. Each of the mappings $\tau^K_t : \mathcal{B}_0^N \to s_G \mathfrak{A}^* \ (|t| \leq \kappa_N)$ can be extended to a unique $^*$-homomorphism of the $C^*$-algebra $\mathcal{B}^N$ into $s_G \mathfrak{A}^*$.
Proof. The mappings $\tau^K_t$ are inner automorphisms of $A$, and their canonical extensions to $A^{**}$ leave the center $\mathcal{Z}$ elementwise invariant. Hence, we can consider $\tau^K_t$ as (inner) automorphisms of $s_GA^{**}$:

$$\tau^K_t \in ^*\text{-Aut} s_GA^{**}, \quad \text{for all } t \in \mathbb{R}, \ K \subset \Pi. \quad (6.2.22)$$

The properties of the $s^*$-limit imply that $\tau^Q_t (|t| \leq \kappa_N, \ t \in \mathbb{R})$ are $^*$-homomorphisms of the symmetric set $\mathfrak{B}^N_0$ into $s_GA^{**}$, as well as they are $^*$-homomorphisms of the minimal $^*$-algebra in $A$ containing $\mathfrak{B}^N_0$ into $s_GA^{**}$. The obvious norm-boundedness of these homomorphisms gives by continuity the wanted (equally denoted) extensions $\tau^Q_t$. \hfill \Box

**Note:** The values $\tau^Q_t(x)$ can be calculated according to the formula (6.2.18) for all $x \in \mathfrak{B}^N$. This is a consequence of the norm-continuity of $C^*$-homomorphisms, and it is easily verified by an elementary calculation.

### 6.2.7 Lemma

Let $|t| \leq \kappa_1$, $\xi \in g$, $E_g(f_\xi) = X_{\xi\Pi} \in s_GA^{**}$, cf. 6.2.2 (ii). Then the limits

$$\tau^Q_t(E_g(f_\xi)) := s^* - \lim_{L \to \infty} \tau^Q_t(X_{\xi\Pi}) \quad (6.2.23)$$

exist.

**Proof.** One has

$$\tau^Q_t(X_{\xi\Pi}) = \sum_{m=0}^{\infty} \frac{(it)^m}{m!} s^* - \lim_{K \to \infty} [Q^K, X_{\xi\Pi}]^{(m)}, \quad (6.2.24)$$

and the bounds (6.2.9) give the estimates independent of $K$ and $L$. After the substitution of $x := X_{\xi\Pi}$ into the sum in (6.2.17), this sum is norm-convergent uniformly in $(K; L) \in \Pi \times \Pi$. Hence we have

$$\tau^Q_t(E_g(f_\xi)) = \sum_{m=0}^{\infty} s^* - \lim_{L} s^* - \lim_{K} [Q^K, X_{\xi\Pi}]^{(m)} \frac{(it)^m}{m!}, \quad (6.2.25)$$

cf. also (6.2.20) and (6.2.21), and the limit (6.2.23) exists (cf. also [40, Proposition 3.5]). \hfill \Box

### 6.2.8

It will be shown next that the elements $E_g(f_\xi)$ ($\xi \in g$) of the algebra $A^{**}$ generate the abelian $C^*$-algebra $\mathfrak{R}^c$ of (bounded continuous) classical observables, cf. 6.2.2(iv), given on the support of $E_g$ in $g^*$. We shall show after this that the transformations $\tau^Q_t$ in (6.2.23) leave this $C^*$-algebra invariant, and that their unique extension for all $t \in \mathbb{R}$ reproduces the classical flow $\varphi^Q$, 6.1.2, restricted to the support supp $E_g$, 5.2.3. These results will lead to a natural definition of the unique extension of $\tau^Q_t : \mathfrak{A}^N \to s_GA^{**}$ for all $t \in \mathbb{R}$, such that these mappings together with the mappings (6.2.23) leave the tensor product $C^N = \mathfrak{A}^N \otimes \mathfrak{R}^c$, 6.2.2(v), invariant, and have a unique extension to a (equally denoted) one parameter group of $^*$-automorphisms of this composite quantal ($\mathfrak{A}^N$) and classical ($\mathfrak{R}^c$) system.

Let $\varphi : g^* \to g^*$ be a Poisson automorphism, (5.2.3), leaving all the $Ad^*$-orbits invariant. Then, using the bicontinuity of $\varphi$ and the $G$-equivariance of the $G$-measure $E_g$, one can prove that the $s_GA^{**}$-valued function $\hat{\varphi}E_g$ of Borel subsets $B \subset g^*$,
\[ \phi E_\theta : B \mapsto \phi E_\theta (B) := E_\theta (\varphi^{-1} B), \quad (6.2.26) \]

is again a projection-valued measure with the same support:

\[ \text{supp } \phi E_\theta = \text{supp } E_\theta. \quad (6.2.27) \]

**6.2.9 Proposition.** Let \( E_\theta \) and \( \varphi \) be as above. Then the mapping

\[ E_\theta : f \mapsto E_\theta (f) := \int f(F) E_\theta (dF), \quad f \in C(\text{supp } E_\theta), \quad (6.2.28) \]

introduced in 6.2.2(ii) is a \( C^* \)-isomorphism of the commutative \( C^* \)-algebra of continuous complex valued functions \( C(\text{supp } E_\theta) \) on the compact subset \( \text{supp } E_\theta \) of \( \mathfrak{g}^* \) (\( X_\xi \)'s are now bounded!) onto \( \mathcal{N}^c \).

The \( C^* \)-algebra \( \mathcal{N}^c \) is generated by the finite set \( E_\theta (f_\xi), \ j = 1, 2, \ldots n \) of its elements (\( \xi_j \)'s form a basis of \( \mathfrak{g} \)). The mapping

\[ \varphi^* : f \mapsto \varphi^* f, \text{ with } \varphi^* f(F) := f(\varphi F), \quad (6.2.29) \]

restricted to \( f \in C(\text{supp } E_\theta) \) is a *-automorphism of \( C(\text{supp } E_\theta) \). One has

\[ \phi : E_\theta (f) \mapsto \phi (E_\theta (f)) := \phi E_\theta (f) = E_\theta (\varphi^* f), \quad f \in C(\mathfrak{g}^*), \quad (6.2.30) \]

and the mapping \( \phi \) in (6.2.30) is a *-automorphism of \( \mathcal{N}^c \).

**Proof.** Since \( \text{supp } E_\theta \) is compact (due to the compactness of spectra of all the \( X_\xi \)'s), the function set \( C(\text{supp } E_\theta) \) is a \( C^* \)-algebra generated by polynomials in the variables \( F_j := F(\xi_j) = f_{\xi_j}(F) \) according to the classical Weierstrass theorem. The *-morphism property of \( E_\theta \) in (6.2.28) is a consequence of the standard functional calculus of normal operators determined by a projection measure. One can show that if \( f(F_0) \neq 0 \) for some \( F_0 \in \text{supp } E_\theta \) and a continuous \( f \), then \( E_\theta (f) \neq 0 \), and this implies that the mapping \( E_\theta \) in (6.2.28) is the \( C^* \)-isomorphism of \( C(\text{supp } E_\theta) \) onto \( \mathcal{N}^c \).

The mapping \( \varphi^* \) is a norm preserving *-morphism of \( C(\text{supp } E_\theta) \) into itself, hence, it is a *-automorphism.

The automorphism property of \( \phi \) in (6.2.30) is then a consequence of the relation (6.2.27), since both the mappings \( E_\theta^{-1} : \mathcal{N}^c \to C(\text{supp } E_\theta) \) and \( \phi E_\theta : C(\text{supp } E_\theta) \to \mathcal{N}^c \) are *-isomorphisms, and we have:

\[ \phi (E_\theta (f)) = \phi E_\theta \circ E_\theta^{-1} (E_\theta (f)), \quad f \in C(\text{supp } E_\theta). \quad (6.2.31) \]

The equality in (6.2.30) can be obtained from (6.2.26) and the integral representation (6.2.28). This concludes the proof. \( \square \)
6.2. SPIN SYSTEMS WITH POLYNOMIAL LOCAL HAMILTONIANS $Q^N$

6.2.10 Proposition. The mappings $\tau^{Q}_t$ introduced in (6.2.23) leave the algebra $\mathcal{N}^c$ invariant. The family $\tau^{Q}_t$ has a unique extension to a strongly continuous one parameter group of $^*$-automorphisms of $\mathcal{N}^c$. This group satisfies the equality

$$\tau^{Q}_t(E_g(f)) = E_g(\varphi^{Q*}_t f), \ f \in C(\text{supp } E_g),$$

(6.2.32)

where $\varphi^{Q}$ is the classical flow corresponding to the Hamiltonian function $Q$, 6.1.2.

Proof. The classical flow $\varphi^{Q}$ forms a group of $\text{Ad}^*$-orbits-preserving Poisson automorphisms of $\mathfrak{g}^*$. According to 6.2.9, the right side of (6.2.32) defines a one parameter group of $^*$-automorphisms of $\mathcal{N}^c$. The strong continuity of this group (i.e. the continuity in the norm of all the functions $t \mapsto E_g(\varphi^{Q*}_t f)$) follows from the differentiability (hence continuity) of

$$\varphi^{Q}: (F; t) \mapsto \varphi^{Q}(F),$$

(6.2.33)

what is uniformly continuous on compacts in $\mathfrak{g}^* \times \mathbb{R}$ ($\mathfrak{g}^*$ is endowed by the linear space topology), as well as from the norm-continuity of the isomorphism $E_g$. Hence, it suffices to prove the validity of the equation (6.2.32) for small $t$.

Let us calculate the limits in (6.2.25). We intend to prove

$$s^*-\lim_L s^*-\lim_K i^m[Q^K, X_{\xi_L}]^{(m)} = E_g(\{Q, f\}_\xi^{(m)}), \ \xi \in \mathfrak{g}, \ m \in \mathbb{Z}_+.$$  

(6.2.34)

Here $\{Q, f\}_0 = f, \{Q, f\}_1 = \{Q, \{Q, f\}_0\}$, and $\{Q, f\}$ is the classical Poisson bracket on the Poisson manifold $\mathfrak{g}^*$. The limits in (6.2.34) do exist, cf. 6.2.5. The local Hamiltonians $Q^K$ are polynomials of the form (6.1.1) and the commutators as well as the Poisson brackets are bilinear, antisymmetric, satisfying the Jacobi identity and the derivation property: $[a, bc] = [a, b]c + b[a, c]$.

We have also

$$s^*-\lim_L s^*-\lim_K i[Q^K, X_{\eta_L}] = s^*-\lim_L X_{[\eta, \xi]}L = E_g(\{f_\xi, f_\eta\}), \ \xi, \eta \in \mathfrak{g}. $$

(6.2.35)

what can be seen from (5.1.5), (6.2.20) and (1.3.12). The morphism properties of $E_g$ then lead to the formula (6.2.34).

Inserting (6.2.34) into (6.2.25), we obtain

$$\tau^{Q}_t(E_g(f_\xi)) = \sum_{m=0}^{\infty} \frac{t^m}{m!} E_g(\{Q, f_\xi\}_\xi^{(m)}).$$

(6.2.36)

The estimates (6.2.9) and the isometry of the mapping $E_g$ from (6.2.28) give, with the help of (6.2.34), the norm-convergence (in the algebra $C(\text{supp } E_g)$) of the sum defining the element $f_{\xi t} \in C(\text{supp } E_g)$:

$$f_{\xi t}(F) := \sum_{m=0}^{\infty} \frac{t^m}{m!} \{Q, f_\xi\}_\xi^{(m)}(F), \ F \in \text{supp } E_g, \ |t| \leq \kappa_1. $$

(6.2.37)

The norm-continuity of the morphism $E_g$ then leads from (6.2.36) to
\[ \tau^Q_t (E_g(f_\xi)) = E_g(f_{\xi t}), \quad \xi \in \mathfrak{g}, \quad |t| \leq \kappa_1 := (M pq^2 b^q a_1)^{-1}. \]  

(6.2.38)

The derivative of the function \( t \mapsto f_{\xi t} \), according to (6.2.37):

\[ \frac{d}{dt} f_{\xi t}(F) = \sum_{m=0}^{\infty} \frac{t^m}{m!} \{ Q, \{ Q, f_\xi \}^{(m)} \}(F), \]  

(6.2.39)

the series in (6.2.39) being again absolutely and uniformly convergent in \( F \in \text{supp } E_g \) and \( |t| \leq \kappa_1, (6.2.9) \), i.e.

\[ (t; F) \in \{ u : u \in \mathbb{R}, \ |u| \leq \kappa_1 \} \times \text{supp } E_g. \]  

(6.2.40)

The classical Hamilton equations written in the form of Poisson brackets for the case of the Hamiltonian function \( Q \) with the flow \( \varphi^Q \) have the form

\[ \frac{d}{du} f(Q^u F) = \{ Q, f \}(Q^u F), \quad F \in \mathfrak{g}^*, \quad u \in \mathbb{R}. \]  

(6.2.41)

Let us substitute \( \varphi^Q_u F \) instead of \( F \) into the formula (6.2.39). From (6.2.41) we obtain

\[ \frac{d}{dt} f_{\xi t}(\varphi^Q_u F) = \sum_{m=0}^{\infty} \frac{t^m}{m!} \frac{d}{du} \{ Q, f_\xi \}^{(m)}(\varphi^Q_u F). \]  

(6.2.42)

The uniform convergence in \( u \in \mathbb{R} \) for any given \( (t; F) \) from (6.2.40) and the known theorem on the differentiation of series of functions lead to the equality:

\[ \frac{d}{dt} f_{\xi t}(\varphi^Q_u F) = \frac{d}{du} f_{\xi t}(\varphi^Q_u F) = \{ Q, f_{\xi t} \}(\varphi^Q_u F), \]  

(6.2.43)

where the second equality was obtained by an application of (6.2.41). Setting \( u = 0 \) in (6.2.43) and comparing with (6.2.41) we get:

\[ f_{\xi t}(F) = f_{\xi 0}(\varphi^Q_t F) \equiv f_\xi(\varphi^Q_t F) = \varphi^Q_t f_\xi(F), \]  

(6.2.44)

since \( f_{\xi 0} = f_\xi \) according to (6.2.37). Insertion of \( f_{\xi t} \) from (6.2.44) into (6.2.38) gives (6.2.32) with \( f := f_\xi (\xi \in \mathfrak{g}) \). The algebra \( C(\text{supp } E_g) \) is generated by \( f_\xi \)'s, and \( \varphi^Q_t \) is a *-isomorphism of \( C(\text{supp } E_g), (6.2.29) \). The norm-continuity of \( C^* \)-morphisms gives then the validity of (6.2.32) for the general \( f \in C(\text{supp } E_g) \).

6.2.11 Lemma. The mappings \( \tau^Q_t (|t| \leq \kappa_N) \) defined in 6.2.5(ii) map the \( C^* \)-algebra \( \mathfrak{A}^N \) into the \( C^* \)-algebra \( \mathfrak{C}^N \) (which is generated in \( s_G \mathfrak{A}^{**} \) by \( \mathfrak{A}^N \) and \( \mathfrak{K}^N \)).

Proof. We can write the definition of \( \tau^Q_t (|t| \leq \kappa_N) \) on \( \mathfrak{A}^N \), (6.2.17) and (6.2.18), in the form

\[ \tau^Q_t (x) := \sum_{m=0}^{\infty} \frac{t^m}{m!} s^* - \lim_{K} \langle i Q^K, x \rangle^{(m)}, \quad x \in \mathfrak{A}^N. \]  

(6.2.45)
Each multiple commutator in (6.2.45) can be expressed in the form of a polynomial in the variables $X_{jK}$ and some of the variables $y_s$ of the form, cf. also (6.2.10) and (6.2.11):

$$y_s := [X_{j_1}^K, [X_{j_2}^K, \ldots [X_{j_s}^K, x] \ldots ]] \in \mathfrak{A}^N, \ K \in \Pi,$$

(6.2.46)

with the coefficients independent of $K$. Due to (6.2.20) and the independence of any $y_s$ of $K$, the strong limits in (6.2.45) are elements of $\mathfrak{C}^N$. The norm convergence of the sum in right hand side of (6.2.45) and the closeness of $\mathfrak{C}$-norm-continuity of $\mathfrak{C}$ in the strong limits in (6.2.45) are elements of $\mathfrak{C}^N$. The norm convergence of the sum in right hand side of (6.2.45) and the closeness of $\mathfrak{C}$ in the norm-topology give then the result. \hfill \qed

6.2.12 Lemma. For any $x \in \mathfrak{A}$ and any $z \in \mathfrak{N}$, the equality $xz = 0$ implies the validity of $\|x\| \cdot \|z\| = 0$.

Proof. For $z \neq 0$, we have $z = E_g(f)$ with $|f(F_0)| \neq 0$ for some $f \in C(\text{supp } E_g)$ and some $F_0 \in \text{supp } E_g$. Let, for the definiteness, be $f(F_0) > 0$. Then there is a subset $B_0 \subseteq \mathfrak{g}^*$ such that $E_g(B_0) \neq 0$ and $f(F) > \frac{1}{2} f(F_0)$ for all $F \in B_0$. Since $\mathfrak{N}$ is in the commutant of $\mathfrak{A}$ in $s_G \mathfrak{A}^{**}$, the product of the positive (i.e. nonnegative) operator $x^*x \in \mathfrak{A}$ with the positive operator $(E_g(f) - \frac{1}{2} f(F_0)) E_g(B_0) \in \mathfrak{N}$ is a nonnegative operator in $\mathfrak{C}$. Then $xz = 0$ implies

$$0 \leq x^*x (E_g(f) - \frac{1}{2} f(F_0)) E_g(B_0) = -\frac{1}{2} f(F_0) x^*x E_g(B_0).$$

(6.2.47)

Hence we have $x E_g(B_0) = 0$. The mapping: $x \mapsto x E_g(B_0)$ is a nonzero (nondegenerate) representation of the simple $C^*$-algebra $\mathfrak{A}$ in $\mathfrak{A}^{**}$, hence $x = 0$. \hfill \qed

6.2.13 Lemma. Let $\mathfrak{A}^N \otimes \mathfrak{N}$ and $\mathfrak{A} \otimes \mathfrak{N}$ be the $C^*$-products (uniquely defined, since $\mathfrak{N}$ is abelian, [274, 1.22.5.]), with the canonical inclusion $\mathfrak{A}^N \otimes \mathfrak{N} \subset \mathfrak{A} \otimes \mathfrak{N}$. Let $\lambda_0^{-1}$ be the homomorphism of $\mathfrak{A} \otimes \mathfrak{N}$ into $\mathfrak{C}$, 6.2.2, determined by the association:

$$\lambda_0^{-1} : \sum_j x_j \otimes z_j \mapsto \sum_j x_j z_j \in \mathfrak{C}, \quad x_j \in \mathfrak{A}, \ z_j \in \mathfrak{N}.$$

(6.2.48)

Then $\lambda_0^{-1}$ can be extended to a unique $^*$-isomorphism $\lambda_0^{-1} := (\lambda_0)^{-1}$ of the $C^*$-algebra $\mathfrak{A} \otimes \mathfrak{N}$ onto $\mathfrak{C}$, the restrictions of which to the subalgebras $\mathfrak{A}^N \otimes \mathfrak{N}$ (N $\in$ $\Pi$) are $^*$-isomorphisms onto $\mathfrak{C}^N$ (N $\in$ $\Pi$), cf. 6.2.2.

Proof. The existence of an isomorphism onto $\mathfrak{C}$ extending $\lambda_0^{-1}$ is a direct consequence of [306, Exercise IV.2], due to our Lemma 6.2.12. The uniqueness is the trivial consequence of the norm-continuity of $C^*$-homomorphisms, since the finite sums in (6.2.48) form dense sets in the corresponding $C^*$-algebras. The same considerations are applicable to the restrictions to $\mathfrak{A}^N \otimes \mathfrak{N}$, hence we have the assertions of the Lemma. \hfill \qed

6.2.14 Lemma. Let $\tau_K$ (K $\in$ $\Pi$), resp. $\tau_{c}$, be a $^*$-homomorphism of $\mathfrak{A}^K$, resp. of $\mathfrak{N}$, into $\mathfrak{C}^K$. Assume that $\tau_{c}(\mathfrak{N}) \subset \mathfrak{N}$. Then there is a unique $^*$-homomorphism $\tau : \mathfrak{C}^K \to \mathfrak{C}^K$ such that:

$$\tau(xz) = \tau_K(x)\tau_{c}(z), \quad \text{for all } x \in \mathfrak{A}^K, \ z \in \mathfrak{N}.$$ 

(6.2.49)
Proof. Let \( \lambda_0 : xz \mapsto x \otimes z \) be the isomorphism of \( \mathcal{C}^K \) onto \( \mathfrak{A}^K \otimes \mathfrak{N}^e \) determined in 6.2.13. According to [306, IV.4.7.], there is a unique homomorphism \( \tau_0 \) of \( \mathfrak{A}^K \otimes \mathfrak{N}^e \) into \( \mathcal{C}^K \) such that
\[
\tau_0(x \otimes z) = \tau_K(x) \tau_e(z), \quad x \in \mathfrak{A}^K, \; z \in \mathfrak{N}^e.
\] (6.2.50)
Since the \( C^* \)-norm on \( \mathfrak{A} \otimes \mathfrak{N}^e \) is a cross norm (see [306, IV.1.]), the \(^*\)-property of \( \tau_0 \) follows from the norm continuity and from the \(^*\)-property of \( \tau_K \) and \( \tau_e \). We shall define \( \tau \) as the composition
\[
\tau := \tau_0 \circ \lambda_0.
\] (6.2.51)
The uniqueness of \( \tau \) is then a consequence of linearity and continuity in the norm-topology. \( \square \)

6.2.15 Proposition. There is a unique family \( \tau^Q := \{ \tau^Q_t ; |t| \leq \kappa_N, \; t \in \mathbb{R} \} \) of \( C^* \)-morphisms of \( \mathcal{C}^N \) into itself such that their restriction to \( \mathfrak{A}^N \subset \mathcal{C}^N \) is given by (6.2.45), and their restriction to \( \mathfrak{N}^e \subset \mathcal{C}^N \) is given by (6.2.32). This family \( \tau^Q \) has a unique extension to an (equally denoted) one parameter group of \( ^* \)-automorphisms of \( \mathcal{C}^N \), for any \( N \in \Pi \).

Proof. After the identification of \( \tau_K \) (resp. \( \tau_e \)) from 6.2.14 with \( \tau^Q_t \) from (6.2.45) (resp. with \( \tau^Q_t \) from (6.2.32)) for any real \( t : |t| \leq r_K \) (\( K \in \Pi \)), the wanted morphism \( \tau^Q_t : \mathcal{C}^K \rightarrow \mathcal{C}^K \) is obtained by its identification with \( \tau \) from (6.2.49). It suffices to prove the group property of these morphisms \( \tau^Q_t \) of \( \mathcal{C}^N \) into itself (with \( N \in \Pi \)) for small \( t \in \mathbb{R} \). Since the restrictions of \( \tau^Q \) to \( \mathfrak{N}^e \) form an automorphism group of \( \mathfrak{N}^e \), and the algebra \( \mathfrak{N}^e \) is in the center of \( \mathcal{C}^N \), it suffices to prove
\[
\tau^Q_{t_1 + t_2}(x) = \tau^Q_{t_2}(\tau^Q_{t_1}(x)) \quad \text{for all} \; x \in \mathfrak{A}^N,
\] (6.2.52)
and for all sufficiently small nonzero \( t_j \) (e.g., for all \( t_j : \max(|t_1|, |t_2|) < \frac{1}{2}\kappa_N \)). For such \( t_j \)'s, we have according to 6.2.5(ii) and (6.2.53):
\[
\tau^Q_{t_1}(\tau^Q_{t_2}(x)) = \tau^Q_{t_1}(s^- \lim_{K \rightarrow \infty} \tau^Q_{t_2}(x)) = \sum_{m=0}^{\infty} \frac{(it_2)^m}{m!} \tau^Q_{t_1}(s^- \lim_{K \rightarrow \infty} [Q^K, x]^{(m)}),
\] (6.2.53)
where the norm continuity of \( \tau^Q_{t_1} \) and the norm-convergence of the series were used. (We write here \( s^- \text{lim} \) instead of \( s^* \text{-lim} \), where the \( s(\mathfrak{A}^*, \mathfrak{A}^*) \)-topology is generated by the seminorms \( p_w \) from (6.2.19). This notation is used for brevity only; the existence and equality of both the limits \( s^- \text{lim} \) and \( s^* \text{-lim} \) is clear from the proof of 6.2.5.) Considering the structure of the multiple commutators in (6.2.53) according to the discussion in the proof of 6.2.11, by the morphism property of \( \tau^Q_{t_1} \) on \( \mathcal{C}^N \) as well as the definition (6.2.23) with (6.2.32) we obtain:
\[
\tau^Q_{t_1}(s^- \text{lim}_K [Q^K, x]^{(m)}) = s^- \text{lim}_K \tau^Q_{t_1}([Q^K, x]^{(m)}),
\] (6.2.54)
\[
= s^- \text{lim}_K [\tau^Q_{t_1}(Q^K), \tau^Q_{t_1}(x)]^{(m)}.
\] (6.2.55)
Since any \(^*\)-morphism \( \tau^Q \) is a contraction, the bounds from 6.2.4 are valid also for the multiple commutators in (6.2.55). From the norm-convergence of the sums we obtain consequently:
\[ \tau^Q_{t_1}(\tau^Q_{t_2}(x)) = s-\lim_{K} \sum_{m=0}^{\infty} \frac{(it_2)^m}{m!} [\tau^Q_{t_1}(Q^K), \tau^Q_{t_1}(x)]^m \]
\[ = s-\lim_{K} \tau^Q_{t_1}(\tau^K_{t_2}(x)). \quad (6.2.56) \]

One has also
\[ \tau^K_{t_2}(x) \in \mathcal{B}^N \text{ for all } x \in \mathfrak{A}^N, \text{ and for all } K \in \Pi. \quad (6.2.57) \]

Then, according to the Lemma 6.2.6 and the formula (6.2.18), one obtains:
\[ \tau^Q_{t_1}(\tau^K_{t_2}(x)) = s-\lim_{L} \tau^L_{t_1}(\tau^K_{t_2}(x)) \]
\[ = s-\lim_{L} \sum_{k,m=0}^{\infty} \frac{(it_1)^k (it_2)^m}{k! m!} [Q^L, [Q^K, x]^{(m)}/(k)]. \quad (6.2.58) \]

The norms of the multiple commutators in (6.2.58) for \( L \geq K \geq N \) are bounded from above according to the estimate (cf. also 6.2.3)
\[ \| [Q^L, [Q^K, x]^{(m)}/(k)] \| \leq \frac{b(x)}{q} (m + k - 1)! (Mpq^2 b^{q-1} a_N)^{m+k}, \]
\[ \text{what can be obtained by the considerations analogous to those used in the proof of 6.2.4. Hence} \]

the sum in (6.2.58) converges in norm, uniformly in \( (K; L) \in \Pi \times \Pi \) with \( L \geq K \geq 1 \). Then the continuity of the product of elements of a \( W^* \)-algebra in the \( s \)-topology leads to:
\[ s-\lim_{K \to \infty} \tau^Q_{t_1}(\tau^K_{t_2}(x)) = s-\lim_{K} \sum_{k,m=0}^{\infty} \frac{(it_1)^k (it_2)^m}{k! m!} [Q^K, [Q^K, x]^{(m)}/(k)] \]
\[ = s-\lim_{K} \sum_{p=0}^{\infty} \frac{(t_1 + t_2)^p}{p!} [iQ^K, x]^{(p)} \]
\[ = s-\lim_{K} \tau^Q_{t_1+t_2}(x) = \tau^Q_{t_1+t_2}(x). \quad (6.2.60) \]

The relations (6.2.56) and (6.2.60) give the desired group property (6.2.52) for all sufficiently small nonzero \( t_1, t_2 \), hence \( \tau^Q \in \text{^* Aut } \mathfrak{C}^N \) (due to the consequent invertibility of \( \tau^Q \) on \( \mathfrak{C}^N \)), and \( \tau^Q \) is a one-parameter group of automorphisms of \( \mathfrak{C}^N \) (for any given \( N \in \Pi \)). \( \square \)

**6.2.16 Note.** We have worked in this section in the framework of the subalgebra \( s_G \mathfrak{A}^{**} \) of the von Neumann algebra \( \mathfrak{A}^{**} \). The only properties of the projector \( s_G \in 3 \) we have used in the previous considerations was the existence of the limits \( X_{\xi N} := s^*-\lim_N s_G X_{\xi N} \) for all \( \xi \in g \) (here the elements \( X_{\xi N} \in \mathfrak{A} \) are identified with \( \pi_{\xi}(X_{\xi N}) \), cf. 6.2.1) as well as the \( \sigma(G) \)-invariance: \( \sigma(g)(s_G) = s_G \) for all \( g \in G \). Any projector \( s_\pi \in 3 \) with these two properties, i.e. \( s_\pi \) such that:
(i) the limits $s^*\lim_N X_{\xi_N}s_\pi$ exist in $s^*(\mathfrak{A}^*,\mathfrak{A}^*)$-topology for all $\xi \in \mathfrak{g}$,

(ii) $s_\pi$ is $\sigma(G)$-invariant: $\sigma(g)(s_\pi) = s_\pi$ for all $g \in G$,

could be used instead of $s_G$ in the considerations of this section. Such projectors form a lattice in $\mathfrak{g}$ with the maximal element $p_G$ defined in 5.1.29. The $G$-measure corresponding to $p_G$ was introduced in 5.1.33 and denoted by $E^\Pi_\mathfrak{g}$. Then the $G$-measure used up to now in this section was $E_\mathfrak{g} = s_G E^\Pi_\mathfrak{g}$, and the $G$-measure $E^\pi_G$ corresponding to another projector $s_\pi \in \mathfrak{g}$ satisfying (i) and (ii) equals to $s_\pi E^\Pi_\mathfrak{g}$. The algebra $\mathfrak{M}_\pi := E^\pi_\mathfrak{g}(C_\mathfrak{g}(\mathfrak{g}^*,\mathbb{C}))$ corresponding to the projector $s_\pi$, hence also the quasilocal algebra $\mathfrak{C}_\pi := \mathfrak{A} \otimes \mathfrak{M}_\pi$, depend nontrivially on the choice of $s_\pi$. If, however, $s_G \leq s_\pi \leq p_G$, then $\mathfrak{M}_\pi$ is isomorphic to $\mathfrak{M}_G$. This is an immediate consequence of the Proposition 6.2.9 as well as of the following Lemma 6.2.17.

6.2.17 Lemma. Let the projector $s_\pi \in \mathfrak{g}$ (:= the center of $\mathfrak{A}^*$) satisfy 6.2.16 (i)+(ii). Let $s_G \leq s_\pi \leq p_G$, and let $E^\pi_\mathfrak{g} := s_\pi E^\Pi_\mathfrak{g}$. Then $\text{supp} E^\pi_\mathfrak{g} = \text{supp} E^\Pi_\mathfrak{g}$ (= $\text{supp} E_\mathfrak{g}$, consequently).

Proof. : Let $sp(X_\xi) \subset \mathbb{R}$ ($\xi \in \mathfrak{g}$) be spectrum of the bounded selfadjoint operator $X_\xi \in \mathcal{L}(\mathcal{H})$. Let $\text{conv}(B)$ be the convex hull of the subset $B$ of a linear space. We have $X_{\xi_N} \in \mathfrak{A}$ ($N \in \Pi$), hence the spectrum $sp(\pi(X_{\xi_N}))$ does not depend of the representation $\pi$ of $\mathfrak{A}$ ($\mathfrak{A}$ is simple). From the construction of $X_{\xi\Pi}$ in 5.1.7 and 5.1.8 we obtain successively:

$$sp(X_{\xi_N}) \subset \text{conv}sp(X_\xi), \quad \xi \in \mathfrak{g}, \quad N \in \Pi,$$

(6.2.61)

what can be seen from [262, Theorem VIII.33]; from the spectral resolution of $X_\xi$ with a help of 5.1.8 one has

$$\{ \lambda \in \mathbb{C} : \lambda = (\varphi, X_\xi \varphi), \| \varphi \| = 1, \varphi \in \mathcal{H} \} = \text{conv}sp(X_\xi) \subset sp(X_{\xi\Pi});$$

(6.2.62)

hence by [262, Theorem VIII.24]:

$$sp(X_{\xi\Pi}) = \text{conv}sp(X_\xi).$$

(6.2.63)

The equality (6.2.63) is independent of such representations $\pi$ of $\mathfrak{A}$ in which (6.2.62) is valid, i.e. for

$$X_{\xi\pi} := s^*\lim_N s_\pi X_{\xi N} \in \mathfrak{A}^*$$

(6.2.64)

we have the implication:

$$\text{conv}sp(X_\xi) \subset sp(X_{\xi\pi}) \Rightarrow sp(X_{\xi\pi}) = \text{conv}sp(X_\xi).$$

(6.2.65)

We have $X_{\xi\Pi} := X_{\xi\pi}$ for $s_\pi := s_G$ and the spectrum of $X_{\xi\pi}$ cannot decrease with increasing $s_\pi$. This proves the conclusion of (6.2.65) for all $s_\pi \geq s_G$, $\xi \in \mathfrak{g}$. Hence the spectra of $X_{\xi\pi}$ are independent of $s_\pi$ for $s_G \leq s_\pi \leq p_G$. The construction of the projection measure $E^\pi_\mathfrak{g}$ according to (5.1.125) and 5.1.33 shows that $F \in \text{supp} E^\pi_\mathfrak{g}$ implies $F(\xi) \in sp(X_{\xi\pi})$:
6.2. SPIN SYSTEMS WITH POLYNOMIAL LOCAL HAMILTONIANS

\[ X_{\xi \pi} = \int F(\xi) E_\pi^\pi(\text{d}F) = E_\pi^\pi(f_\xi). \]  

(6.2.66)

This formula shows also that \( \lambda \in \text{sp}(X_{\xi \pi}) \) implies the existence of such an \( F \in \text{supp} E_\pi^\pi \) that \( F(\xi) = \lambda \). We shall show in the next Lemma that \( \text{supp} E_\pi^\pi \) is a convex subset of \( \mathfrak{g}^* \). Let

\[ B_\pi := \{ F \in \mathfrak{g}^* : F(\xi) \in \text{convsp}(X_\xi), \forall \xi \in \mathfrak{g} \}. \]  

(6.2.67)

The set \( B_\pi \) is convex and closed in \( \mathfrak{g}^* \). We have

\[ \text{supp} E_\pi^\pi \subset B_\pi \text{ for any } s_\pi \geq s_G \text{ (} s_\pi \leq p_G \text{)}. \]  

(6.2.68)

Let \( B = \overline{B} = \text{conv}B \subset B_\pi \) be such that for any \( \xi \in \mathfrak{g} \) the following implication is valid:

\[ \lambda \in \text{convsp}(X_\xi) \Rightarrow \exists F \in B : F(\xi) = \lambda. \]  

(6.2.69)

The set \( B := \text{supp} E_\pi \), and also \( B := B_\pi \) has the property (6.2.69).

Let \( F_0 \in \mathfrak{g}^* \) does not belong to \( B : F_0 \not\in B \). Then, according to [157, Lemma(B.26)], there is an element of \( \mathfrak{g}^{**} = \mathfrak{g}^*, \xi_0 \in \mathfrak{g}^*, \) such that

\[ \inf \{ F(\xi_0) : F \in B \} > F_0(\xi_0). \]  

(6.2.70)

But from (6.2.69) and from \( B \subset B_\pi \) we see that \( \{ F(\xi) : F \in B \} = \text{convsp}(X_\xi) \) for all \( \xi \in \mathfrak{g} \), hence \( F_0(\xi_0) \not\in \text{convsp}(X_{\xi_0}) \), and this implies that \( F_0 \not\in B_\pi \). We have proved that \( B = B_\pi \), hence \( \text{supp} E_\pi = B_\pi \). But

\[ s_G \leq s_\pi \Rightarrow E_\pi \leq E_\pi^\pi \Rightarrow \text{supp} E_\pi \subset \text{supp} E_\pi^\pi, \]  

(6.2.71)

what with the help of (6.2.68) gives now the desired result.

\[ \square \]

6.2.18 Lemma. \( \text{supp} E_\pi \) is convex.

Proof. The projection measure \( E_\pi \) introduced in 6.2.2.(i) is built of its values \( E_\pi(F) \), (5.1.56), calculated on one point sets \( \{ F \} \subset \mathfrak{g}^* \). The measure \( E_\pi \) is isomorphically mapped onto the measure \( E_\pi^\#: = \rho_G \circ E_\pi \) acting in the Hilbert subspace \( P_G \mathcal{H}_\Pi \) of the infinite (complete) tensor product space \( \mathcal{H}_\Pi \), cf. 5.1.11. According to the definitions in 5.1.7, 5.1.9 and 5.1.11, \( F \in \text{supp} E_\pi \) means that there is a product-vector \( \Psi \in \mathcal{H}_\Pi \):

\[ \Psi := \bigotimes_{k \in \Pi} \varphi_k, \varphi_k \in \mathcal{H}_k := u_k \mathcal{H}, \| \varphi_k \| = 1, \text{ for all } k \in \Pi, \]  

(6.2.72)

such that the following relations are valid:

\[ \lim_{N \to \infty} \frac{1}{N} \sum_{k=1}^{N} (\varphi_k, \pi_k(X_\xi)\varphi_k) = F(\xi), \text{ for all } \xi \in \mathfrak{g}. \]  

(6.2.73)
Let $F^{(j)} \in \text{supp } E_g$ ($j = 1, 2$) be determined according to (6.2.73) by the product vectors $\Psi^{(j)} := \otimes_{k \in \Pi} \pi_k^{(j)} \in D_{\Pi}(g)$. We shall construct a product vector $\Psi \in D_{\Pi}(g)$, for any rational number $c : 0 < c = \frac{r}{s} < 1$, such that the corresponding value of $F \in g$, cf. (6.2.72) and (6.2.73), is

$$F = cF^{(1)} + (1 - c)F^{(2)}. \quad (6.2.74)$$

This will prove the convexity of $\text{supp } E_g$, since $\text{supp } E_g$ is a closed subset of $g^*$. We shall construct the sequence \{\varphi_k : k \in \Pi\} defining $\Psi$ according to (6.2.72) from the sequence \{\varphi_k^{(j)} : k \in \Pi, \ j = 1, 2\} for any two natural numbers $0 < r < s$ as follows:

$$\varphi_{ms+j} := \varphi_{mr+j}^{(1)}, \text{ for } j = 1, 2, \ldots r; \ m \in \mathbb{Z}_+;$$

$$:= \varphi_{m(s-r)+j-r}^{(2)}, \text{ for } j = r+1, r+2, \ldots s; \ m \in \mathbb{Z}_+. \quad (6.2.75)$$

(Here we have identified $\mathcal{H}_k$ with $\mathcal{H}$ ($k \in \Pi$). The formally correct rewriting of the formula (6.2.75) includes, e.g., $\varphi_{ms+j} := u_{ms+j}u_{mr+j}^{-1}\varphi_{mr+j}$.)

Let

$$\Psi_k^{(j)}(\xi) := (\varphi_k^{(j)}, \pi_k(X_\xi)\varphi_k^{(j)}), \ j = 1, 2; \ \Psi_k(\xi) := (\varphi_k, \pi_k(X_\xi)\varphi_k). \quad (6.2.76)$$

Inserting from (6.2.75) into the left hand side of (6.2.73) we obtain:

$$\frac{1}{ms+j} \sum_{k=1}^{ms+j} \Psi_k(\xi) = \frac{1}{ms+j} \sum_{k=1}^{j} \Psi_{ms+k}(\xi)$$

$$+ \frac{ms}{ms+j} \left( \frac{r}{m} \sum_{k=1}^{mr} \Psi_k^{(1)}(\xi) + \frac{s-r}{s} \sum_{k=1}^{m(s-r)} \Psi_k^{(2)}(\xi) \right). \quad (6.2.77)$$

Taking the limit $m \to \infty$ on both sides of (6.2.77) ($j \in \{1, 2, \ldots s\}$), we obtain (6.2.74). \hfill \Box

6.2.19 Proposition. Let $s_\pi \leq p_G$ be a $\sigma(G)$-invariant projector in the center $\mathfrak{z}$ of $\mathfrak{A}^*$. Let $E_\pi^\sigma := s_\pi E_\pi$ be the corresponding $G$-measure. Then $\mathcal{M}_\pi := E_\pi^\sigma(C_b(g^*, \mathbb{C})) \subset \mathcal{N}_\pi$, cf. 6.2.2(iv). Specifically, $\mathcal{M}_\pi = \mathcal{N}_\pi$ for $s_\pi \geq s_G$. (Here we have identified $^\ast$-isomorphic $C^*$-algebras.)

Proof. If $s_{\pi j}$ ($j = 1, 2$) are two such projectors $s_\pi$ with $s_{\pi 1} \leq s_{\pi 2}$, then for the corresponding $G$-measures one has $\text{supp } E_{\pi 1}^\sigma \subset \text{supp } E_{\pi 2}^\sigma \subset \text{supp } E_g$, cf. 6.2.17. The Proposition 6.2.9 and its proof is applicable to any $G$-measure in the case of bounded generators $X_\xi$ ($\xi \in g$). Since $C(\text{supp } E_{\pi 1}^\sigma) \subset C(\text{supp } E_{\pi 2}^\sigma) \subset C(\text{supp } E_g)$, and $\mathcal{M}_\pi = E_\pi^\sigma(C(\text{supp } E_{\pi 1}^\sigma))$ is an isomorphic image of $C(\text{supp } E_g)$, the result follows. \hfill \Box

Note: With a help of this proposition one can show that $s_G$ can be replaced by $s_\pi$, with $s_G \leq s_\pi \leq p_G$, everywhere in this Section 6.2.
6.2.20 Theorem. Let $A := A^\Pi$ be the quasilocal algebra introduced in 5.1.4; $\sigma(G) \subset \text{*-Aut } A$ is generated by the continuous unitary representation $U(G)$ in $\mathcal{H}$ of a Lie group $G$ with bounded generators $X_\xi = X_\xi^*$ ($\xi \in \mathfrak{g}$), cf. 5.1.5 and 5.1.3. Let $s_\pi \leq p_G$ be a $\sigma(G)$-invariant central projector in $A^\sigma$, where $p_G$ is introduced in 5.1.29. Let $E_\emptyset := s_\pi F_\emptyset^\Pi$, where $E_\emptyset$ is defined in 5.1.33. Let $\Omega_\pi^N$ and $C_\pi$ be defined as in 6.2.16 and $E_\pi^N := A^\emptyset \otimes \Omega_\pi^N$; the algebras $\Omega_\pi^N$, $C_\pi^N$, and $C_\pi$ are considered as $C^*$-subalgebras of $s_\pi A^\sigma$ in the canonical way, cf. 6.2.1, 6.2.2 and 6.2.13. Let $Q$ be a polynomial with the property (SA) of 6.1.1. Then one has:

(i) The sequence $\{\tau^K : K \in \Pi\}$ of the one parameter *-automorphism groups of $A$ generated by $Q^K$ according to (6.1.2) determines a unique one parameter group $\tau^Q \subset \text{*-Aut } C$ (with $C := C_\pi$ for $s_\pi := p_G$) such that for any $N \in \Pi$ and for all $|t| \leq \kappa_N$ (cf. (6.2.16))

$$\tau_i^Q(x) = \lim_{K \to \infty} \tau_i^K(x), \quad \forall x \in A^N := p_G \pi_u(A^N). \quad (6.2.78)$$

The $s^*(p_G A^\sigma, p_G A^\sigma)$-topology is determined by the seminorms from (6.2.19) with $\omega \in S_s(p_G A^\sigma)$.

(ii) The $C^*$-subalgebras $\Omega_\pi^N$, $C_\pi$ and $C_\pi^N$ ($N \subset \Pi, \: s_\pi \leq p_G$) of $C$ are invariant with respect to $\tau^Q$. Let the restriction of $\tau^Q$ to $C_\pi$ be denoted by $\tau^\pi$. (Note: We have changed the notation here. It was denoted by $\tau^Q$ the group $\tau^\pi$ with $s_\pi := s_G$ in the preceding subsections.)

(iii) The restriction of $\tau^\pi$ to $N_\pi$ reproduces the classical flow $\varphi^Q$ corresponding to the Hamiltonian function $Q$ on the Poisson manifold $\mathfrak{g}^*$ in the sense that

$$\tau_i^\pi(E_\emptyset^\pi(f)) = E_\emptyset^\pi(\varphi_i^Q f), \quad f \in C(\mathfrak{g}^*). \quad (6.2.79)$$

(iv) The group $\tau^Q$ is a strongly continuous subgroup of $\text{*-Aut } C$, i.e. the functions

$$t \mapsto \tau_i^Q(y) \quad (6.2.80)$$

are norm-continuous for all $y \in C$: The triple $\{C, \mathbb{R}, \tau^Q\}$ is a $C^*$-dynamical system, [53, 2.7.1].

(v) $\tau^\pi$ (for any $s_\pi$ specified above) is a $\sigma(C_\pi, s_\pi A^\sigma)$-continuous group of automorphisms of $C_\pi$, i.e. the functions

$$t \mapsto \omega(\tau_i^\pi(y)) \quad (6.2.81)$$

are continuous for all states $\omega \in s_\pi A^\sigma$ ($:= \{f \in A^\sigma : f(s_\pi x) = f(x), \forall x \in A^\sigma\}$) and for all $y \in C_\pi$, and for all such $\omega$ one has:

$$\omega \circ \tau_i^\pi \in s_\pi A^\sigma, \quad \forall t \in \mathbb{R}. \quad (6.2.82)$$
(vi) The infinitesimal generator of $\tau^\pi$ is the \textbf{derivation} $\delta_\pi$ on $\mathfrak{C}_\pi$ such that

$$
\delta_\pi(y) = i \sum_{j=1}^n E_\pi^\pi(\partial_j Q) [X^N_j, y], \text{ for all } y \in \mathfrak{A}^N, \quad (6.2.83a)
$$

$$
\delta_\pi(E_\pi^\pi(f)) = E_\pi^\pi(\{Q, f\}) \text{ for } f \in C^1(\mathfrak{g}^*), \quad (6.2.83b)
$$

where the square bracket in (6.2.83a) is the commutator, and $\mathfrak{A}^N$ is considered there as $s_\pi\pi_u(\mathfrak{A}^N)$ ($\mathfrak{A}$ is simple!), and the partial derivatives $\partial_j Q$ denote the differentiation of $Q$, with respect to the components $F_j := F(\xi_j)$ of $F \in \mathfrak{g}^*$ in the dual basis to the basis $\{\xi_j : j = 1, 2, \ldots n\}$ of $\mathfrak{g}$, $X_j := X_{\xi_j}$. The compound bracket in right hand side in (6.2.83b) denotes the classical Poisson bracket on $\mathfrak{g}^*$. The operator $\delta_\pi$ determined by (6.2.83) determines the group $\tau^\pi \in ^*\text{-Aut} \mathfrak{C}_\pi$ uniquely:

$$
\tau^\pi_t(y) = \sum_{m=0}^\infty \frac{t^m}{m!} \delta^m_\pi(y), \text{ for all } y \in \mathfrak{B}^#, |t| \leq \kappa_N, N \in \Pi. \quad (6.2.84)
$$

\textbf{Proof.} We shall use here the fact mentioned in the Note in 6.2.19 that in the assertions of this section we can replace $s_G$ by $p_G$; we shall refer to the assertions and their proofs in Sec.6.2 as if they were reformulated with this replacement.

(i) The restrictions of $\tau^Q$ to the subalgebras $\mathfrak{C}^N_i$ given in 6.2.15 determine a unique group $\tau^Q \subset ^*\text{-Aut} \mathfrak{C}$, since each of the mappings

$$
\tau^Q_i : y \mapsto \tau^Q_i(y), \quad y \in \mathfrak{C}^N, \quad N \in \Pi, \quad t \in \mathbb{R}, \quad (6.2.85)
$$

is norm-continuous and $\{y : y \in \mathfrak{C}^N, N \in \Pi\}$ is norm-dense in $\mathfrak{C}$.

(ii) After the replacement of $s_G$ by $s_\pi$ (hence also $E_\pi^\pi$ by $E_\pi^\pi$) in 6.2.10 and 6.2.15 we obtain the invariance of $\mathfrak{M}_\pi$ and of $\mathfrak{C}_\pi$ due to $\sigma(G)$-equivariance of $E_\pi^\pi_G$. The $\tau^Q$-invariance of $\mathfrak{C}^N_i$ is clear.

(iii) Immediately from 6.2.10, since $\tau^\pi_t(E_\pi^\pi(f)) = s_\pi \tau^Q_t(E_\pi^\pi(f))$.

(iv) It suffices to prove the continuity in (6.2.80) for $t \to 0$. With $y := x \in \mathfrak{A}^N$ the continuity is given by the uniform convergence in (6.2.45), and this implies the continuity for all $x \in \mathfrak{A}$ (by an $\epsilon/3$- argument). For $y := E_\pi^\pi(f), \ f \in C(\text{supp } E_\pi^\pi)$, it suffices to prove

$$
\lim_{t \to 0} \|\varphi^Q_t f - f\| = 0, \quad (6.2.86)
$$

since $f \mapsto E_\pi^\pi(f)$ is a $C^*$-morphism. The validity of (6.2.86) is a consequence of the joint continuity of the classical flow $\varphi^Q$,

$$
\varphi^Q : (t; F) \mapsto \varphi^Q_t(F) \in \mathfrak{g}^*, \quad (6.2.87)
$$
as well as of the compactness of \( E^\pi_0 \) and of the continuity of \( f \).

(v) The continuity in (6.2.81) is a consequence of (iv). Let us consider \( \tau^\pi_t \) \( (t \in \mathbb{R}) \) as a family of representations of \( \mathfrak{A} := \pi_u(\mathfrak{A}) \subset \mathfrak{A}^{**} \) in the subalgebra \( s_{\pi} \mathfrak{A}^{**} \) of \( \mathfrak{A}^{**} \). The unique \( \sigma(\mathfrak{A}^{**}, \mathfrak{A}^{*}) - \sigma(s_{\pi} \mathfrak{A}^{**}, s_{\pi} \mathfrak{A}^{*}) \)-continuous extensions of these representations to \( \mathfrak{A}^{**} \), \cite[1.21.13]{274}, will be denoted by \( \tau^\pi_t \) (resp. \( \tau^\pi_t \) for \( s_{\pi} < p_G \)). From 6.2.10 and from its proof one can see

\[
\overline{\tau}_{\pi}^\pi(s_{\pi}) = \tau^\pi_t(E^\pi_0(g^*)) = s_{\pi}. \tag{6.2.88}
\]

We have also \( \tau^\pi_t(id_\mathfrak{A} - s_{\pi}) = 0 \), and the restrictions of \( \tau^\pi_t \) \( (t \in \mathbb{R}) \) to the \( \tau^\pi_t \)-invariant subalgebra \( s_{\pi} \mathfrak{A}^{**} \) form a family of \(*\)-automorphisms which are automatically \( \sigma \)-continuous, \cite[4.1.23]{274}. The definition \( \tau^\pi \) with a help of strong limits, cf. (6.2.23), shows that the restriction of \( \overline{\tau}_{\pi}^\pi \) to \( \mathfrak{C}_{\pi} \) coincides with the above defined \( \tau^\pi_{\pi} \in *-\text{Aut} \mathfrak{C}_{\pi} \). This proves the normality of \( \omega \circ \tau^\pi_t \) for any normal \( \omega \) (i.e. \( \omega \in s_{\pi} \mathfrak{A}^{*} \)), hence (6.2.82).

(vi) The automorphism group \( \tau^\pi \) of \( \mathfrak{C}_{\pi} \) is determined uniquely by the determination of \( \tau^\pi_t(x) \) for all \( x \in \mathfrak{B}^N \) (cf. Lemma 6.2.6 and 6.2.2(iii) for notation), for \( |t| \leq \kappa_N, N \in \Pi \); this is clear from 6.2.5 and from its consequences. The series in the formula

\[
\frac{d}{dt}\tau^\pi_t(x) = i \sum_{m=0}^{\infty} \frac{(it)^m}{m!} s^* - \lim_{K} [Q^K, [Q^K, x]^{(m)}] \tag{6.2.89}
\]

converges uniformly in the disc \( |t| \leq \kappa_N \) \( (x \in \mathfrak{B}^N) \), hence the equality (6.2.89) is valid. Considerations similar to those used in the dealing with (6.2.58) lead to the equalities:

\[
s^* - \lim_{K} [iQ^K, [iQ^K, x]^{(m)}] = s^* - \lim_{K} s^* - \lim_{L} [iQ^L, [iQ^K, x]^{(m)}] = s^* - \lim_{K} \delta_{\pi}([iQ^K, x]^{(m)}), \tag{6.2.90}
\]

where for all \( N \in \Pi \):

\[
\delta_{\pi}(x) := s^* - \lim_{L} i[Q^L, x], \text{ for all } x \in \mathfrak{B}^N := s_{\pi} \pi_u(\mathfrak{B}^N). \tag{6.2.91}
\]

The derivation property of commutators and the polynomial form of \( Q \) together with (6.2.20) lead to the expression (6.2.83a) for \( \delta_{\pi} \) in (6.2.91). Setting \( t = 0 \) in (6.2.89), we see that so defined \( \delta_{\pi}(x) \) is the value of the generator \( \delta_{\pi} \) of \( \tau^\pi \) on \( x \in \mathfrak{A}^N \) \( (N \in \Pi) \). By the differentiation of (6.2.32) with \( f \in C^1(\text{supp } E^\pi_0) \) we obtain (6.2.83b), cf. (6.2.43) and notes in \cite{53} above 3.2.29. From the continuity properties of \( \tau^\pi \) and the corresponding closedness of \( \delta_{\pi} \), cf. \cite[3.1.6]{53}, we obtain by the repeated use of (6.2.90):

\[
s^* - \lim_{K} \delta_{\pi}([iQ^K, x]^{(m)}) = \delta_{\pi}(s^* - \lim_{K} [iQ^K, x]^{(m)}) = \delta_{\pi}^{m+1}(x). \tag{6.2.92}
\]

Insertion from (6.2.91) and (6.2.92) into (6.2.45), cf. the note following (6.2.53), gives for \( x \in \mathfrak{B}^N \), \( |t| \leq \kappa_N \) the norm-convergent series:
\[ \tau_\pi^\gamma(x) = \sum_{m=0}^\infty \frac{t^m}{m!} \delta_\pi^m(x). \]  

(6.2.93)

This proves that the operator \( \delta_\pi \) from (6.2.83) determines \( \tau_\pi^\gamma \). \( \square \)

6.3 Time evolution in generalized mean-field theories

6.3.1. We shall construct in this section a general class of time evolutions \( \tau^Q \) of the infinite quantum systems \( (\mathfrak{A}; \sigma(G)) \) defined in Sec.5.2. The time evolution \( \tau^Q \) is determined in a canonical way by an arbitrary classical Hamiltonian function \( Q \) on the (generalized) homogeneous classical phase space \( g^* \) as well as by the automorphism group \( \sigma(G) \) of \( \mathfrak{A} \). It will be shown later that the here presented construction leads to the same evolution what was denoted by \( \tau^Q \) in Sec.6.2. in the case of \( A := A^\Pi \), \( \sigma(G) \) being defined according to 5.1.5, and with \( Q \) being a polynomial in a basis of \( g^* \) dual to any fixed basis \( \{\xi_j, j = 1, 2, \ldots n\} \); the generators of the continuous representation \( U(G) \) in the 'one-spin space' \( \mathcal{H}, 5.1.3, \) are supposed to be bounded in this special case.

We shall start with the general case, the specifications to the cases considered in Sec.5.1, and the further specification to the cases of Sec.6.2 will be made later on. Let us fix here some general assumptions valid throughout of this section.

Using the notation of Sec.5.2, let \( E_g \) be a fixed nontrivial \( G \)-measure associated with the system \( (\mathfrak{A}; \sigma(G)) \) such that, with \( p_G := E_g(g^*) \), the following implication is valid:

\[ \omega \in p_G S(\mathfrak{A}) =: S_g \Rightarrow g \in G \mapsto \omega(\sigma(g)(x)) \text{ is continuous for all } x \in \mathfrak{A}. \]  

(6.3.1)

It will be shown in 6.3.10 that this assumption is fulfilled by \( \sigma(G) \) from 5.1.5 with \( p_G \) from 5.1.29. We shall assume that \( \mathfrak{A} \) is a unital \( C^* \)-algebra which is simple (this last assumption is made only for brevity of our expression). The nontriviality of \( E_g \) means a certain 'breaking of symmetries' occurring in the system, cf. our 5.2.3 for basic definitions, and for illustration of the phenomenon of “spontaneous symmetry breaking” see [106, 265], [53, Sec. 4.3.4], [41, IV.A], 6.5.5.

The time evolution \( \tau^Q \) will be defined with a help of the group-valued function \( g_Q(t,F) \) on \( \mathbb{R} \times g^* \) defined in 6.1.3 with (6.1.17) (another possible choice of \( \beta^Q_F \) will not change the general construction of \( \tau^Q \), so that the nonuniqueness of \( \beta^Q_F \) leads to various possibilities for the definition of the time evolutions \( \tau^Q \)). The notation introduced in 6.1.2 and 6.1.3 will be used here. Let us note that the equation (6.1.16) for \( g_Q \) can be written in any continuous unitary representation \( U(G) \) in \( \mathcal{H} \) in the form

\[ i \frac{d}{dt} U(g_Q(t,F)) = X(\beta^Q_F) U(g_Q(t,F)), \quad F \in g^*, \quad t \in \mathbb{R}, \]  

(6.3.2)

where \( F_t := \varphi^Q_t(F) ; \quad X(\xi) := X\xi \ (\xi \in g) \) are the selfadjoint generators of \( U(G) \), and \( \beta^Q_F \in g \) was introduced in 6.1.3. The equation (6.3.2) is of the form of (linear) quantum-mechanical evolution equation with the time-dependent Hamiltonian operator \( X(\beta^Q_{F_t}) \). The equation (6.3.2)
describes, in the setting of Sec.5.1, the time evolution of any 'individual' quantum subsystem placed in any fixed site \( k \in \Pi \) in the surrounding 'mean field' \( \varphi^Q_t(F) \in \mathfrak{g}^* \) generated by the whole collection of the quantal subsystems (for all the sites \( k \in \Pi \)) interacting by an 'infinitely weak and of infinitely long-range' interaction with each other. The equation (6.3.2) will be useful in the analysis of thermodynamic properties of the considered systems.

6.3.2 Definitions.

(i) \( C_b := C_b(\text{supp } E_{\mathfrak{g}}, \mathbb{C}) \) will denote the set of all uniformly bounded complex-valued continuous functions on \( \text{supp } E_{\mathfrak{g}} \subseteq \mathfrak{g}^* \), see 5.2.3 for the definition of \( \text{supp } E_{\mathfrak{g}} \).

(ii) The \( s^* \)-topology on \( \mathfrak{A} \) is determined by seminorms \( p_\omega, p^*_\omega \) (cf. (6.2.19)) for all \( \omega \in p_G \mathcal{S}(\mathfrak{A}) \).

(iii) Let \( C_{bs} := C_{bs}(\text{supp } E_{\mathfrak{g}}, \mathfrak{A}) \) be the set of all \( \mathfrak{A} \)-valued, uniformly bounded \( s^* \)-continuous functions on \( \text{supp } E_{\mathfrak{g}} \), i.e. \( f \in C_{bs} \) means that the function

\[
\begin{align*}
f : F(\in \text{supp } E_{\mathfrak{g}}) &\mapsto f(F) \ (\in \mathfrak{A}) \\
\|f\| &:= \sup\{\|f(F)\| : F \in \text{supp } E_{\mathfrak{g}}\} < \infty,
\end{align*}
\]

and all the functions

\[
\begin{align*}
F &\mapsto \omega((f(F) - f(F_0))^*(f(F) - f(F_0))), \ \omega \in p_G \mathcal{S}(\mathfrak{A}), \ F_0 \in \text{supp } E_{\mathfrak{g}}, \ (6.3.5a) \\
F &\mapsto \omega((f(F) - f(F_0))(f(F) - f(F_0))^*), \ \omega \in p_G \mathcal{S}(\mathfrak{A}), \ F_0 \in \text{supp } E_{\mathfrak{g}}, \ (6.3.5b)
\end{align*}
\]

converge to zero for \( F \) converging to \( F_0 \) in the norm-topology of \( \mathfrak{g}^* \).

(iv) For any \( \sigma(G) \)-invariant \( C^* \)-subalgebra \( \mathfrak{A}^J \) of \( \mathfrak{A} \):

\[
\sigma(g)(x) := \sigma_g(x) \in \mathfrak{A}^J \text{ for all } x \in \mathfrak{A}^J, \ g \in G,
\]

let \( C_{bs}^J := C_{bs}(\text{supp } E_{\mathfrak{g}}, \mathfrak{A}^J) \) be defined equally as it was defined \( C_{bs} \) in (iii) with the replacement of \( \mathfrak{A} \) by \( \mathfrak{A}^J \).

(v) Let \( C_{bs}^G \) (resp. \( C_{bs}^{GJ} \)) be the \( C^* \)-subalgebra (cf. 6.3.4) of \( C_{bs} \) (resp. of \( C_{bs}^J \)) generated by all the functions \( f_0 \in C_{bs} \) of the form

\[
\begin{align*}
f_0 : F &\mapsto \sigma_{g_0(F)}(x) f(F), \ f \in C_b, \ g_0 \in C(\text{supp } E_{\mathfrak{g}}, G),
\end{align*}
\]
with any \( x \in \mathfrak{A} \) (resp. any \( x \in \mathfrak{A}' \)). The set \( C(\text{supp } E_g, G) \) consists of all continuous \( G \)-valued functions on \( \text{supp } E_g \).

(vi) We shall use also \( K := \text{supp } E_g \), resp. \( K \subset \mathfrak{g}^* \) will denote any \( \text{Ad}^*(G) \)-invariant closed subset of the generalized classical phase space in more general cases. We shall identify \( C_b := C_b(K, \mathbb{C}) \) with the subset \( \mathcal{C}_{bs}(K, \mathbb{C}, \text{id}_\mathfrak{A}) \) of \( \mathcal{C}_{bs} \) in the canonical way: \( f \in C_b \) is identified with the function

\[
f : F \mapsto \text{id}_\mathfrak{A} f(F), \quad F \in K, \quad \text{id}_\mathfrak{A} \text{ is the identity of } \mathfrak{A}.
\] (6.3.8)

6.3.3 Proposition. The set \( \mathcal{C}_{bs} \) is a *-algebra with respect to the natural (pointwise) algebraic operations determined by the corresponding operations in the range \( \mathfrak{A} \) of the elements \( f \in \mathcal{C}_{bs} \):

\[
(f_1 + \lambda f_2)(F) := f_1(F) + \lambda f_2(F), \quad (f_1 f_2)(F) := f_1(F) f_2(F), \quad f^*(F) := [f(F)]^*, \quad \forall F \in K, \lambda \in \mathbb{C}, \quad f_j \text{ and } f \in \mathcal{C}_{bs},
\] (6.3.9)

and it is a normed algebra with the norm \( \|f\| \) of \( f \in \mathcal{C}_{bs} \) given by (6.3.4). This normed *-algebra \( \mathcal{C}_{bs} \) is a \( C^* \)-algebra, and its subsets \( \mathcal{C}_{bs}' \) and \( C_b \) endowed with the induced algebraic operations and the norm are \( C^* \)-subalgebras of \( \mathcal{C}_{bs} \).

Proof. The continuity properties of the product in \( \mathfrak{A} \) with respect to the \( s^* \)-topology are given by Proposition 1.8.12. and Theorem 1.8.9. of [274]. Then the uniform boundedness of \( f \in \mathcal{C}_{bs} \) and the continuity of the *-operation in the \( s^* \)-topology gives the invariance of \( \mathcal{C}_{bs} \) with respect to the algebraic operations (6.3.9). The norm properties of the function given in (6.3.4) are easily verified, and the \( C^* \)-property of the norm:

\[
\|f\|^2 = [\sup_F \|f(F)\|]^2 = \sup_F \|f(F)\|^2 = \sup_F \|f(F)^* f(F)\| = \|f^* f\|,
\] (6.3.10)

is valid too. We shall verify completeness of \( \mathcal{C}_{bs} \) in this norm. For any Cauchy sequence \( \{f_n, n \in \mathbb{Z}_+\} \) in \( \mathcal{C}_{bs} \), the sequence \( \{f_n(F), n \in \mathbb{Z}_+\} \) is Cauchy in \( \mathfrak{A} \) for any \( F \in K \). The completeness of \( \mathfrak{A} \) gives the existence of pointwise limits

\[
f(F) := \lim_{n \to \infty} f_n(F) \in \mathfrak{A}, \quad F \in K.
\] (6.3.11)

By defining the norm of any function \( f : K \to \mathfrak{A} \) (\( \|f\| \) could be infinite in general) by (6.3.4), we have the norm-convergence of \( f_n \) to \( f \) from (6.3.11): If \( \|f_n - f_m\| < \delta \) for all \( n, m > n_\delta \), then \( \|f_n - f\| < \delta \) for all \( n > n_\delta \), for any positive \( \delta \), since \( \lim_{m \to \infty} \|f_n(F) - f_m(F)\| = \|f_n(F) - f(F)\| \) for all \( F \in K \). Considering the cyclic representation \( (\pi_\omega, \mathcal{H}_\omega, \Omega_\omega) \) corresponding to any \( \omega \in p_G \mathcal{S}(\mathfrak{A}) \) as a subrepresentation of the universal representation \( \pi_u \) in \( p_G \pi_u (\mathfrak{A}) \), we have with the identification of \( \mathfrak{A} \) with \( p_G \pi_u (\mathfrak{A}) \) (cf. (6.2.19)):

\[
p_\omega (f(F) - f(F_0)) = \|(f(F) - f(F_0)) \Omega_\omega\| \leq 2 \|f_m - f\| + \|(f_m(F) - f_m(F_0)) \Omega_\omega\|,
\] (6.3.12)
and the s-continuity of \( f_m \)'s gives the s-continuity of \( f \). A use of the norm-continuity of the *-operation gives us the \( s^* \)-continuity of \( f \), i.e. \( f \in \mathcal{C}_{bs} \). The remaining assertions of the proposition follow now easily.

**6.3.4 Lemma.** The functions \( f_0 \) from (6.3.7) belong to \( \mathcal{C}_{bs} \). Hence, \( \mathcal{C}_{bs}^G \) and \( \mathcal{C}_{bs}^{GJ} \) are \( C^* \)-subalgebras of \( \mathcal{C}_{bs} \).

**Proof.** Since \( f \in C_b \) can be considered as an element of \( \mathcal{C}_{bs} \), it suffices to prove \( f_0 \in \mathcal{C}_{bs} \) for \( f_0 \) given by (6.3.7) with \( f := \) constant function. This will be proved by proving the \( s^* \)-continuity of \( \sigma(G) \). For any \( x \in \mathfrak{A} \) and any \( \omega \in p_G\mathcal{S}(\mathfrak{A}) \), we have

\[
p_\omega (\sigma_g(x) - \sigma_{g_0}(x))^2 = \omega ((\sigma_g(x^*) - \sigma_{g_0}(x^*)) (\sigma_g(x) - \sigma_{g_0}(x))) = \omega (\sigma_g(x^*) - \sigma_{g_0}(x^*) + (\sigma_g(x^*) - \sigma_{g_0}(x^*)) \sigma_{g_0}(x)) + \omega (\sigma_{g_0}(x^*) (\sigma_{g_0}(x) - \sigma_g(x))) ,
\]

and the s-continuity follows from the assumption (6.3.1) by repeated use of the polarization identity (expressing nondiagonal matrix elements of bounded operators in a Hilbert space by a finite linear combination of the diagonal ones). The \( s^* \)-continuity is then obtained by the replacement of \( x \) by \( x^* \) in the above considerations.

**6.3.5.** The quasilocal \( C^* \)-algebra \( \mathfrak{A} \) of quantum (microscopic) observables is naturally embedded into \( \mathcal{C}_{bs} \) as a \( C^* \)-subalgebra by the identification of any \( x \in \mathfrak{A} \) with a constant function \( f \in \mathcal{C}_{bs}^G \):

\[
f(F) := x = 1(F) \sigma_e(x), \ F \in K, \quad (6.3.14)
\]

where \( 1(F) := 1 \) for all \( F \in \mathfrak{g}^* \). The classical (macroscopic) observables are embedded into \( \mathcal{C}_{bs}^G \) according to the formula (6.3.8), where the classical observables are represented by functions belonging to \( C_b(K, \mathbb{C}) \). We can (and we shall) consider \( \mathcal{C}_{bs}^G \), or \( \mathcal{C}_{bs} \), as the (extended) \( C^* \)-algebra of observables of the systems with ‘mean-field’ dynamics. It might be useful, however, to embed this new algebra of observables in a canonical way into the \( \mathcal{W}^* \)-algebra \( \mathfrak{A}^{**} \), since there is a canonical bijection between the set of all states \( \omega \in \mathcal{S}(\mathfrak{A}) \) and the set of all normal states \( \omega \in \mathcal{S}_s(\mathfrak{A}^{**}) \) on the double dual \( \mathfrak{A}^{**} \) of \( \mathfrak{A} \): any \( \omega \in \mathcal{S}(\mathfrak{A}) \) corresponds to its (equally denoted) canonical normal extension \( \omega \in \mathcal{S}_s(\mathfrak{A}^{**}) \). Hence, after obtaining an embedding of \( \mathcal{C}_{bs} \) into \( \mathfrak{A}^{**} \) such that \( \mathfrak{A} \subset \mathcal{C}_{bs} \) is mapped onto \( \pi_u(\mathfrak{A}) \subset \mathfrak{A}^{**} \) or onto its subrepresentation, we shall obtain a certain canonical extension of any state \( \omega \in \mathcal{S}(\mathfrak{A}) \) (or of any state \( \omega \in p_G\mathcal{S}(\mathfrak{A}) \), where \( p_G \in \mathfrak{g} \) is the projector onto the above mentioned subrepresentation of \( \pi_u \) to a state on \( \mathfrak{A}^{**} \) (resp. on \( p_G\mathfrak{A}^{**} \)), and this in turn gives to us a certain canonical extension of states on \( \mathfrak{A} \) to states on \( \mathcal{C}_{bs} \). Such an embedding is given in the following proposition.

**6.3.6 Proposition.** Let us consider the integral decomposition of any \( \omega \in p_G\mathcal{S}(\mathfrak{A}^{**}) \) [where \( \mathfrak{A} \) is simple] given by the formula (5.1.146) according to Theorem 5.2.11, and let \( E_g : \mathcal{M} \to \mathfrak{g}^* \) be given as in 5.1.39. There is a \( C^* \)-isomorphism of \( \mathcal{C}_{bs} \) into \( p_G\mathfrak{A}^{**} \) formally written in the form

\[
E_g : f(\in \mathcal{C}_{bs}) \mapsto E_g(f) := \int f(F) E_g(dF), \quad (6.3.15)
\]
where \( E_{\mathfrak{g}} \) denotes the \( G \)-measure (as before) as well as the presently introduced isomorphism. The isomorphism \( E_{\mathfrak{g}} \) is uniquely determined by the formula\(^2\)

\[
\omega(E_{\mathfrak{g}}(f)) := \int \omega_m(f(F_m)) \mu_\omega(dm), \quad \forall \omega \in p_G \mathcal{S}_s(\mathfrak{A}^{**}),
\]

(6.3.16)

where the decomposition (5.1.146) was used, and (cf. 5.1.39)

\[
F_{\mathfrak{g}} : m \mapsto F_m := F_{\mathfrak{g}}(m), \quad m \in \mathcal{N} \subset \mathcal{M},
\]

(6.3.17)

is defined on the spectrum space \( \mathcal{N} \) of the (commutative) subalgebra \( \mathfrak{N}(E_{\mathfrak{g}}) \) of \( p_G \mathfrak{A}^{**} \), cf. 5.2.3.

The mapping \( E_{\mathfrak{g}} \) leaves \( \mathfrak{A} := p_G \pi_u(\mathfrak{A}) \) invariant and maps \( \mathcal{C}_b \) onto a \( \mathcal{C}^* \)-subalgebra \( \mathcal{N}_c \) of \( \mathfrak{N}(E_{\mathfrak{g}}) =: \mathfrak{N}_G \), see also 5.2.10.

**Proof.** Let \( B \subset \mathcal{N} \) be any Borel set and \( \chi_B \) is its characteristic function. The functions

\[
m \mapsto \omega_m(x) \chi_B(m), \quad x \in \mathfrak{A}^{**},
\]

(6.3.18)

are Borel functions on \( \mathcal{N} \) for any \( \omega \in p_G \mathcal{S}_s(\mathfrak{A}^{**}) \). Since the function \( F_{\mathfrak{g}} \) in (6.3.17) is continuous, the measurability of the functions

\[
m \mapsto \omega_m(f \circ F_{\mathfrak{g}}(m)), \quad f \in \mathcal{C}_b,
\]

(6.3.19)

can be proved with a help of a sequence \( F_{\mathfrak{g}}(n) \) of functions from \( \mathcal{N} \) into the one point compactification \( \hat{\mathfrak{g}}^* \) of \( \mathfrak{g}^* \) assuming each only a finite number of values and pointwise converging to \( F_{\mathfrak{g}} \) in the natural topology of \( \hat{\mathfrak{g}}^* \). Then the functions

\[
m \mapsto \omega_m(f \circ F_{\mathfrak{g}}^{(n)}(m)), \quad f \in \mathcal{C}_b, \quad \omega \in p_G \mathcal{S}_s(\mathfrak{A}^{**})
\]

(6.3.20)

are finite sums of functions of the form (6.3.18), hence the functions (6.3.20) are measurable. The \( s^* \)-continuity of \( f \) implies then the pointwise convergence of the functions (6.3.20) to the function (6.3.19) for \( n \to \infty \). According to a known theorem in measure theory, cf. e.g. [223, 6.I0.VII.], the pointwise limit of uniformly bounded measurable functions is measurable, hence (6.3.19) are Borel functions. We have proved the existence of the integrals in (6.3.16) for any \( f \in \mathcal{C}_b \). The function

\[
E_{\mathfrak{g}}(f) : \omega \in \mathfrak{S}(\mathfrak{A}) \mapsto \omega(E_{\mathfrak{g}}(f)) \in \mathbb{C},
\]

(6.3.21)

is affine: The extension mapping \( e_* \) of \( \mathfrak{S}(\mathfrak{A}) \) onto \( \mathfrak{S}_s(\mathfrak{A}^{**}) \) is affine, and the association of subcentral (hence orthogonal, hence regular Borel) measures to the states \( \omega \in \mathfrak{S}_s(\mathfrak{A}^{**}) \) defined by (cf. (5.1.147))

\[
\hat{\mu} : \omega \mapsto \hat{\mu}_\omega \in \{\text{probability measures on } \mathfrak{S}(\mathfrak{A}^{**})\},
\]

(6.3.22)

\(^2\)Note: For noncompact \( \text{supp } E_{\mathfrak{g}} \), the integral is a limit of integrals over bounded subsets \( B \subset \mathfrak{g}^* \): 
\[ \int \omega_m(E_{\mathfrak{g}}(B)f(F_m)) \mu_\omega(dm). \]
where the measure $\hat{\mu}_\omega$ corresponds to the decomposition of $\omega \in \mathcal{S}(\mathfrak{A}^{**})$ given by the commutative subalgebra $\pi_\omega(\mathfrak{M}_G)''$ in $\mathcal{L}(\mathcal{H}_\omega)$ (cf. [53, 4.1.25.], and for the definition of $\mathfrak{M}_G$ see 5.2.10), is also affine. The affinity of (6.3.22) can be proved on the basis of the fact that all the measures in (6.3.22) are obtained from the same algebra $\mathfrak{M}_G \subset \mathfrak{F}$ by considering $\hat{\mu}_\omega$ and $\lambda_1\hat{\mu}_{\omega_1} + \lambda_2\hat{\mu}_{\omega_2}$ (with $\omega := \lambda_1\omega_1 + \lambda_2\omega_2$) as limits of the nets of measures which correspond to the net of finite dimensional subalgebras of $\mathfrak{M}_G$, compare Lemma 4.1.26. in [53]:

$$\omega(x) = \sum_j \omega(p_j x) = \lambda_1 \sum_j \omega_1(p_j x) + \lambda_2 \sum_j \omega_2(p_j x), \quad \sum_j p_j = \text{id}_\mathfrak{A}, \quad (6.3.23)$$

for any finite set of mutually orthogonal projectors $p_j \in \mathfrak{M}_G$. Hence, (6.3.22) is an affine mapping:

$$\hat{\mu}_\omega = \lambda_1\hat{\mu}_{\omega_1} + \lambda_2\hat{\mu}_{\omega_2}, \quad \text{for } \omega := \lambda_1\omega_1 + \lambda_2\omega_2. \quad (6.3.24)$$

The relation (6.3.24) has a unique extension to all $\omega_j \in \mathfrak{A}^*$ ($\lambda_j \in \mathbb{C}$). Writing for $\omega \in p_G\mathcal{S}(\mathfrak{A})$:

$$\omega(E_0(f)) = \int \varphi(f(F_0 \circ r_M(\varphi))) \hat{\mu}_\omega(d\varphi), \quad (6.3.25)$$

what is meaningful for $\varphi \in \text{supp} \hat{\mu}_\omega$ (cf. the proof of 5.1.38), we obtain now affinity of (6.3.21) which can be uniquely extended to linearity on the whole $\mathfrak{A}^*(\mathfrak{A}^{**})$. The boundedness of the mapping (6.3.21) is a direct consequence of (6.3.25) as well as of the boundedness of the function $f$. This proves that $E_0(f) \in \mathfrak{A}^{**}$, where the linear extension of (6.3.21) is denoted by the same symbol. We shall consider $\mathfrak{A}^{**}$ as a $W^*$-algebra in the canonical way: $\mathfrak{A}^{**} := \pi_u(\mathfrak{A})'' \subset \mathcal{L}(\mathcal{H}_u)$. We shall prove the morphism property of $E_0$ in (6.3.15). The linearity of (6.3.15) is clear from (6.3.16) and from the linearity of each of $\omega_m$. By a 'polarization procedure' one can prove

$$\omega(E_0(f)y) = \int \omega_m(f(F_m)y) \mu_\omega(dm), \quad y \in \mathfrak{A}^{**}, \quad \omega \in p_G\mathcal{S}_*(\mathfrak{A}^{**}). \quad (6.3.26)$$

Since $\omega_m(yE_0(f)) = \omega_m(yf(F_m))$ for all $\omega \in p_G\mathcal{S}_*(\mathfrak{A}^{**})$, $m \in \text{supp} \mu_\omega$, $y \in \mathfrak{A}^{**}$ and $f \in \mathfrak{C}_{bs}$, we have also

$$\omega(E_0(f_1)E_0(f_2)) = \int \omega_m(f_1(F_m)E_0(f_2)) \mu_\omega(dm) \quad (6.3.27)$$

$$= \int \omega_m(f_1(F_m)f_2(F_m)) \mu_\omega(dm) = \omega(E_0(f_1f_2),$$

which proves $E_0(f_1f_2) = E_0(f_1)E_0(f_2)$ for all $f_j \in \mathfrak{C}_{bs}$ ($j = 1, 2$). The $^*$-property follows by the decomposition of $f \in \mathfrak{C}_{bs}$ into the real and imaginary parts in (6.3.16).

We shall show that the kernel of the morphism $E_0 : \mathfrak{C}_{bs} \rightarrow p_G\mathfrak{A}^{**}$ is trivial. We shall use here the simplicity of the $C^*$-algebra $\mathfrak{A}$. Let $f > 0$ be a positive element of $\mathfrak{C}_{bs}, \|f\| > 0$. If $f(F_0) \neq 0, F_0 \in K$, then there is a state $\omega \in \mathcal{S}(\mathfrak{A})$ with $\omega(f(F_0)) \neq 0$. The s-continuity of $f \in \mathfrak{C}_{bs}$ implies that the set
CHAPTER 6. MATHEMATICAL STRUCTURE OF QM MEAN-FIELD THEORIES

\[ B := \{ F \in K : \omega(f(F)) > \frac{1}{2} \omega(f(F_0)) \} \subset g^* \]  

(6.3.28)

is open in \( K := \text{supp} E_g \). Hence \( E_g(B) \neq 0 \), and

\[ \| f(F) \| > \frac{1}{2} |\omega(f(F_0))| > 0, \text{ for all } F \in B. \]  

(6.3.29)

Any state \( \omega_0 \in \mathcal{S}(\mathfrak{A}) \) supported by \( E_g(B) : \omega_0(x) = \omega_0(E_g(B)x) (x \in \mathfrak{A}) \), is decomposed according to (5.1.146) into the states \( \omega_m \) with \( F_m \in B \) for all \( m \in \text{supp} \mu_{\omega_0} \). Since \( \mathfrak{A} \) is simple, there is an element \( x_m \in \mathfrak{A} \) for any such \( \omega_m \) that

\[ \omega_m(x_m^* x_m) = 1, \text{ and } \omega_m(x_m^* f(F_m)x_m) \neq 0. \]  

(6.3.30)

The state \( \varphi_m \in \mathcal{S}(\mathfrak{A}) \), \( \varphi_m(y) := \omega_m(x_m^* y x_m) \) is also supported by \( E_g(B_m) \) with any open \( B_m \subset K \) containing \( F_m \). Hence the decomposition (5.1.146) of \( \omega := \varphi_m \) is concentrated on the one point set \( \{ m \} \). This means that

\[ \varphi_m(E_g(f)) := \varphi_m(f(F_m)) \neq 0, \]  

(6.3.31)

hence \( E_g(f) \neq 0 \) for any nonzero \( f \in \mathcal{C}_{bs} \). This proves the isometry of \( E_g \), hence \( E_g \) is a \( C^* \)-isomorphism of \( \mathcal{C}_{bs} \) into \( E_g(g^*) \mathfrak{A}^{**} = p_G \mathfrak{A}^{**} \). The remaining assertions are clearly valid. \( \square \)

6.3.7 Lemma. Let \( f \in \mathcal{C}_{bs}, \omega \in p_G \mathcal{S}(\mathfrak{A}). \) Then the function

\[ (g; F) \mapsto \omega\left(\sigma^{-1}_g(f(F))\right) \in \mathbb{C}, (g; F) \in G \times K, \]  

(6.3.32)

is jointly continuous on the topological product \( G \times \text{supp} E_g \).

Proof. Let \( f := f_0, \) cf. (6.3.7). Then

\[ \sigma^{-1}_g(f_0(F)) = \sigma(g^{-1}g_0(F))(x)f(F), \]  

(6.3.33)

and the joint continuity of the group operation

\[ (g_1; g_2) (\in G \times G) \mapsto g_1^{-1}g_2 \in G \]  

(6.3.34)

gives the joint continuity in (6.3.32) with \( f := f_0 \). It can be verified directly, cf. e.g. (6.3.13), that the function in (6.3.33) is even \( s^* \)-continuous in the couple \( (g; F) \in G \times K \). But the finite algebraic combinations as well as the uniform limits of \( s^* \)-continuous bounded functions are \( s^* \)-continuous. Since \( \mathcal{C}_{bs}^G \) is generated by functions of the form \( f_0 \), we have proved that the functions

\[ (g; F) \mapsto \sigma^{-1}_g(f(F)) \in \mathfrak{A}, \text{ for all } f \in \mathcal{C}_{bs}^G, \]  

(6.3.35)

are even \( s^* \)-continuous. \( \square \)
6.3.8 Proposition. Let, with the notation of 6.1.3, be \( f \in \mathfrak{C}_{bs} \), and for any \( t \in \mathbb{R} \), \( F \in K \), let

\[
f_t(F) := \sigma(g_Q^{-1}(t))(f(\varphi_Q^0 F)).
\]

Then \( f_t \in \mathfrak{C}_{bs} \) and the mappings \( f \mapsto f_t \) form a one-parameter group of \(*\)-automorphisms of \( \mathfrak{C}_{bs} \): \( f_{t+s} = (f_t)_s \), for all \( t, s \in \mathbb{R} \).

Proof. From the continuity properties of \( g_Q \) and \( \varphi_Q \) (\( g_Q \) and \( \varphi_Q \) depend smoothly on \( t \) and \( F \)), and from the \( s^*\)-continuity of functions (6.3.35), we have \( f_t \in \mathfrak{C}_{bs} \) for any \( f \in \mathfrak{C}_{bs} \). The \(*\)-morphism properties of the mapping \( f \mapsto f_t \) are fulfilled due to the morphism properties of the pull-back \( \varphi^* \) by any diffeomorphism \( \varphi \) of \( K \),

\[
\varphi^* : f \mapsto \varphi^* f, \quad \varphi^* f(F) := f(\varphi F), \quad F \in K \subset \mathfrak{g}^*,
\]

as well as of \( \sigma(g) \in \ast\-\text{Aut} \mathfrak{A} \). The group property follows immediately from the group property of the flow \( \varphi^Q \) and from the cocycle property (6.1.13) of \( g_Q \). The group property implies invertibility, hence isometry of the considered mappings.

6.3.9. We have just proved existence of a certain 'time evolution' in the \( C^*\)-algebra \( \mathfrak{C}_{bs} \) containing \( \mathfrak{A} \) and \( \mathfrak{R}^c \). This evolution is determined by an arbitrary classical Hamiltonian function \( Q \) and by the representation \( \sigma(G) \) of the group \( G \) of 'macroscopic symmetries' with the help of the formula (6.3.36). To have possibility to see connections with the 'mean-field evolutions' discussed in Sec.6.2, we shall transfer this evolution into \( \mathfrak{A}^{**} \) by a use of the isomorphism \( E_{\mathfrak{g}} \) from (6.3.15). We shall see that the time evolutions defined by a limiting procedure in Sec.6.2 can be defined directly by the formula (6.3.36) (transferred into \( p_G \mathfrak{A}^{**} \)). The same possibility of a definition of 'mean-field evolutions' arises in all the systems considered in Sec.5.1. To make this possibility clear, let us prove the property (6.3.1) for those systems.

6.3.10 Lemma. Let us consider the systems determined with a help of infinite tensor product considered in Sec.5.1. Then the group \( \sigma(G) \subset \ast\-\text{Aut} \mathfrak{A} \) (\( \mathfrak{A} := \mathfrak{A}^\Pi \)) has the property (6.3.1): The functions \( g \mapsto \sigma_g(x) \) on \( G \) are \( s^*\)-continuous for all \( x \in \mathfrak{A} \), the \( s^*\)-continuity being determined by the seminorms \( p_\omega \) and \( p_\omega^* \) from (6.2.19) with \( \omega \in p_G \mathcal{S} \mathfrak{A} \), and \( p_G \) was defined in 5.1.29.

Proof. The implication "(6.3.1) \( \Rightarrow s^*\)-continuity" was proved in Lemma 6.3.4. Since the set of local elements \( x \in \bigcup_{N \in \Pi} \mathfrak{A}^N \) is norm-dense in \( \mathfrak{A} \), it suffices to prove the continuity in (6.3.1) for \( x \) local. We have assumed in 5.1.29 the existence of the generators \( X_\xi^N (\xi \in \mathfrak{g}, N \subset \Pi) \) of all one parameter subgroups of the unitary group \( V_N(G) \) acting in \( H_N \), cf. 4.3.8 and 5.1.2, as well as the existence of (equally denoted) generators for the unitary groups \( p_G \pi_u(V_N(\exp(\xi t))) \) for all \( \xi \in \mathfrak{g} \). For \( \omega \in p_G \mathcal{S} \mathfrak{A} \) and \( x \in \mathfrak{A}^N \) we have

\[
\omega(\sigma(\exp(\xi t))(x)) = (\Omega_\omega, \exp(-itX_\xi^N)\pi_u(x) \exp(itX_\xi^N)\Omega_\omega), \quad (6.3.38)
\]

what continuously depends on \( t \). We have to prove the strong-continuity of the group \( U(g) := p_G \pi_u(V_N(g)) \) from the strong continuity of all one parameter subgroups \( U(\exp \xi t) =: \exp(-itX_\xi), \quad (\xi \in \mathfrak{g}) \); we write here \( X_\xi \) instead of \( X_\xi^N \). Let \( \xi_j \in \mathfrak{g}, \quad j = 1, 2, \ldots n \) be a fixed basis in \( \mathfrak{g} \).
and set $X_j := X_{E_j}$. Let us parametrize $g \in G$ in a neighbourhood of the unity $e \in G$ by $t := (t_1, t_2, \ldots, t_n) \in \mathbb{R}^n$ in the following way, cf [152, Lemma II.2.4]:

$$g \equiv g(t) := \exp(t_1 \xi_1) \exp(t_2 \xi_2) \ldots \exp(t_n \xi_n).$$  

(6.3.39)

Now we can prove weak continuity of $U(g(t))$ in $t = 0 \in \mathbb{R}^n$ from the known strong continuity of $U_j(t) := U(\exp \xi_j t) = \exp(-itX_j)$, for all $j = 1, 2, \ldots, n$. Since $U$ is a representation of $G$, we can write

$$U(g(t)) - I = \prod_{j=1}^n U_j(t_j) - I = \sum_{k=1}^n \left[ \prod_{j=1}^{k-1} U_j(t_j) \right] (U_k(t_k) - I),$$  

(6.3.40)

where $I$ is the unit operator in the Hilbert space of the representation and the product of zero number of factors equals to $I$. Since the unitary operators do not change the norm of vectors, we have for any unit vectors $\Psi_1$ and $\Psi_2$ in the Hilbert space:

$$|\langle \Psi_1, (U(g(t)) - I) \Psi_2 \rangle| \leq \sum_{k=1}^n \| (U_k(t_k) - I) \Psi_2 \|. \quad (6.3.41)$$

This estimate gives weak, hence strong continuity of $U(g)$.

6.3.11 Definition. Let $E_0$ be the *-isomorphism of $\mathcal{C}_{bs}$ into $p_G \mathfrak{A}^{**}$ described in (6.3.15). Let $\tau_t^Q \in * \text{- Aut } p_G \mathfrak{A}^{**}$ ($t \in \mathbb{R}$) denote the one-parameter group determined by

$$\tau_t^Q(E_0(f)) := E_0(f_t), \quad t \in \mathbb{R}, \quad f \in \mathcal{C}_{bs}^G,$$  

(6.3.42)

where $f_t \in \mathcal{C}_{bs}^G$ was introduced in (6.3.36). The uniqueness of the extension of (6.3.42) to the whole $p_G \mathfrak{A}^{**}$ is given by uniqueness of the normal extension of the representations $\tau_t^Q : \mathfrak{A} \to p_G \mathfrak{A}^{**}$ to the representations of $\mathfrak{A}^{**}$ in $p_G \mathfrak{A}^{**}$, [274, 1.21.13], and the automorphism property of these extensions is given by the $\tau^Q$-invariance of $p_G$ (hence, $\tau_t^Q(id_{\mathfrak{A}^{**}} - p_G) = 0$ for all $t$ and $Q$). The automorphism group $\tau^Q$ will be called the mean-field time evolution of the system $(\mathfrak{A}; \sigma(G))$ determined by the classical Hamiltonian function $Q$.

6.3.12 Theorem. Let $E_0$ be a nontrivial $G$-measure associated with the system $(\mathfrak{A}; \sigma(G))$, cf. 5.2.3, with $K := \text{supp } E_0 \subset \mathfrak{g}^*$ such that $\sigma(G) \in * \text{- Aut } \mathfrak{A}$ is $\sigma(\mathfrak{A}, p_G \mathfrak{A}^*)$-continuous ($p_G := E_0(K)$). Let $\tau^Q \subset * \text{- Aut } E_0(\mathcal{C}_{bs}^G)$ be the mean-field time evolution of $(\mathfrak{A}; \sigma(G))$ determined by any $Q \in C^\infty(\mathfrak{g}^*, \mathbb{R})$. Let $\mathfrak{N}^J$ be any $\sigma(G)$-invariant $C^*$-subalgebra of $\mathfrak{A}$. Then:

(i) $\mathfrak{N}^c := E_0(C_b)$ and $\mathfrak{N}^J := E_0(\mathcal{C}_{bs}^J)$ are $\tau^Q$-invariant $C^*$-subalgebras of the 'algebra of mean-field observables' $\mathfrak{C} := E_0(\mathcal{C}_{bs}^G) \subset p_G \mathfrak{A}^{**}$.

(ii) $\tau^Q$ is a $\sigma(\mathfrak{C}, S_0)$-continuous group, i.e. for any $y \in \mathfrak{C}$ and for any $\omega \in p_G S_0(\mathfrak{A}^{**}) := S_0$ the function $t \mapsto \omega(\tau_t^Q(y))$ is continuous and the states $\omega \circ \tau_t^Q : y \mapsto \omega(\tau_t^Q(y))$ belong to $S_0$, $\omega \circ \tau_t^Q \in p_G \mathfrak{A}^*$. 

(iii) Let \( \{\xi_j : j = 1, \ldots, n\} \) be a fixed basis of \( \mathfrak{g} \) and \( F_j := F(\xi_j) \) be the coordinates of \( F \in \mathfrak{g}^* \) in the dual basis. Let \( \partial \xi_j : \mathfrak{A} \to \mathfrak{A} \) be the derivations (defined on \( \sigma(\mathfrak{A}, p_G \mathfrak{A}^*) \)-dense domains in \( \mathfrak{A} \)) of the one parameter subgroups \( \sigma(\exp t \xi_j) \) of \( \sigma(G) \). Then the infinitesimal generator of the group \( \tau^Q \) is the derivation \( \delta_Q \) on \( \mathfrak{C} \) expressed by:

\[
\delta_Q(E_g(f)) := \frac{d}{dt} \bigg|_{t=0} \tau^Q_t(E_g(f)) = \sum_{j=1}^n \int (\partial_j f(F)(Q,F_j)(F) - \partial_j Q(F) \delta_Q(f(F))) \ E_g(dF),
\]

where the derivation is taken in the \( \sigma(\mathfrak{C}, \mathfrak{S}_g) \)-topology, the symbol \( \partial_j f(F) \) means the derivative of a function on \( \mathfrak{g}^* \) with respect to the variable \( F_j \) in the point \( F \in \mathfrak{g}^* \), and the meaning of the integral is explained in 6.3.6. \( \{Q, F_j\} \) is here the Poisson bracket on \( \mathfrak{g}^* \), 6.1.2.

(iv) If the group \( \sigma(G) \) is strongly continuous (i.e. \( g \mapsto \sigma_g(x) \) is continuous in norm for each \( x \in \mathfrak{A} \)), and if \( K \) is compact, then the group \( \tau_t^Q \) will be strongly continuous.

Proof. The group \( \tau^Q \) is considered here as an automorphism group of the \( \tau^Q \)-invariant subalgebra \( E_g(\mathfrak{C}_G^{\delta_s}) := \mathfrak{C} \) of \( p_G \mathfrak{A}^{**} \).

(i) The invariance of \( \mathfrak{A}^c \) is given by the invariance of \( C_0 \) with respect to the transformations (6.3.36), which is valid due to the invariance of scalars in \( \mathfrak{A} \) with respect to \( \sigma(G) \): \( \sigma_g(\lambda \text{id}_{\mathfrak{A}}) = \lambda \text{id}_{\mathfrak{A}} \), \( \lambda \in \mathbb{C}, \forall g \in G \). Similarly, the relation \( \sigma(G)(\mathfrak{A}^I) = \mathfrak{A}^I \) gives the \( \tau^Q \)-invariance of \( \mathfrak{A}^I \).

(ii) The continuity of the functions \( t \mapsto \omega(\tau^Q_t(y)) \) (\( \omega \in \mathfrak{S}_g, \ y \in \mathfrak{C} \)) can be obtained from the definition of the evolution \( f \mapsto f_t \) in \( \mathfrak{C}_G^{\delta_s} \) as well as from the definition (6.3.16) of \( E_g(f) \) as follows:

Due to the \( s^* \)-bicontinuity of the mappings (6.3.35) and due to the (bi-)continuity of the functions \( g_0 \) and \( \varphi^Q \), the functions

\[
\Psi(m) : t \mapsto \Psi_t(m) := \omega_m(f_t(F_m)), \ m \in \text{supp } \mu_\omega,
\]

are continuous for any fixed \( \omega \in \mathfrak{S}_g \) and \( f \in \mathfrak{C}_G^{\delta_s} \). We have proved in (6.3.19) the measurability of all the functions \( \Psi_t : m \mapsto \Psi_t(m) \). Since \( |\Psi_t(m)| \leq \|f\| \) (\( t \in \mathbb{R}, \ m \in \text{supp } \mu_\omega \)) and \( \mu_\omega \) is finite, an application of the Lebesgue dominated convergence theorem gives

\[
\lim_{t \to 0} \omega(\tau^Q_t(E_g(f))) = \lim_{t \to 0} \int \Psi_t(m) \mu_\omega(dm) = \int \Psi_0(m) \mu_\omega(dm) = \omega(E_g(f)). \quad (6.3.45)
\]

This gives the desired continuity.

Any \( \tau_t^Q \) can be considered as a \(*\)-automorphism of the \( W^* \)-algebra \( p_G \mathfrak{A}^{**} \), and each such automorphism is \( \sigma(p_G \mathfrak{A}^{**}, \mathfrak{S}_g) - \sigma(p_G \mathfrak{A}^{**}, \mathfrak{S}_g) \)-continuous, cf. [274, 4.1.23]. This implies that the
state \( \omega \circ \tau_t^Q \) is a normal state on \( p_G \mathfrak{A}^{**} \) together with \( \omega \), hence \( \omega \in \mathcal{S}_g \) implies that \( \omega \circ \tau_t^Q \in \mathcal{S}_g \).

(iii) We shall calculate the derivation \( \delta_Q \) from (6.3.43) by calculating the derivatives of the functions \( \Psi(m) \) in (6.3.44). For ‘sufficiently nice’ elements \( E_g(f) \in D(\delta_Q) (:= \text{the domain of } \delta_Q) \) we have:

\[
\frac{d}{dt} \bigg|_{t=0} \omega(f_t(F)) = \frac{d}{dt} \bigg|_{t=0} \omega(f(\varphi_t^Q F)) + \frac{d}{dt} \bigg|_{t=0} \omega \left( \sigma(g_Q^{-1}(t, F))(f(F)) \right). \tag{6.3.46}
\]

For the calculation of the first term we shall use the classical evolution equation (6.2.41), where we shall consider \( f(F) \) as a function of coordinates \( \varphi_t^Q \) and \( \varphi_t^Q F(\xi_j) \):

\[
\frac{d}{dt} f(\varphi_t^Q F) = \sum_{j=1}^n \partial_j f(\varphi_t^Q F) \frac{d}{dt} F_j(\varphi_t^Q F) = \sum_{j=1}^n \partial_j f(\varphi_t^Q F) \{Q, F_j\}(\varphi_t^Q F). \tag{6.3.47}
\]

Insertion of \( f(F) := \omega(f(F)) \) into (6.3.47) and setting \( t = 0 \) we obtain:

\[
\frac{d}{dt} \bigg|_{t=0} \omega(f(\varphi_t^Q F)) = \sum_{j=1}^n \partial_j \omega(f(F)) \{Q, F_j\}(F). \tag{6.3.48}
\]

The second term in (6.3.46) can be calculated with a help of (6.1.10) + (6.1.17) + (6.1.18), and by considering that for any \( \xi \in \mathfrak{g} \) we have defined:

\[
\frac{d}{dt} \bigg|_{t=0} \omega(\sigma(\exp t\xi)(x)) = \omega(\delta\xi(x)), \quad x \in D(\delta\xi) \subset \mathfrak{a}. \tag{6.3.49}
\]

One obtains:

\[
\frac{d}{dt} \bigg|_{t=0} \omega(\sigma(g_Q(t, F))(x)) = \sum_{j=1}^n \partial_j Q(F) \omega(\delta\xi_j(x)), \quad x \in \bigcap_{j=1}^n D(\delta\xi_j). \tag{6.3.50}
\]

Combining (6.3.48) and (6.3.50), where we set \( \omega := \omega_m, \quad F := F_m \) and \( x := f(F_m) \), we obtain for the ‘sufficiently nice’ \( f \in C^g_{Qb} \):

\[
\frac{d}{dt} \bigg|_{t=0} \omega(\tau_t^Q E_g(f)) = \sum_{j=1}^n \int \omega_m \left( \partial_j f(F_m) \{Q, F_j\}(F_m) - \partial_j Q(F_m) \delta\xi_j(f(F_m)) \right) \mu_\omega(dm). \tag{6.3.51}
\]

The change of the sign is caused by the replacement of \( g_Q \) by \( g_Q^{-1} \) in (6.3.50). The comparison of (6.3.43) with (6.3.51) gives the result.

(iv) We have to prove that the functions:

\[
t \mapsto \|f_t - f\| \quad \text{for all } f \in C^g_{Qb} \tag{6.3.52}
\]
are continuous at $t = 0$. Let us write

$$\|f_t(F) - f(F)\| = \|\sigma^{-1}(g_Q(t, F))(f(\varphi^Q_t F)) - f(F)\| \leq$$

$$\leq \|\sigma(g_Q^{-1}(t, F))(f(F) - f(F_0))\| + \|\sigma(g_Q^{-1}(t, F))(f(F_0)) - f(F_0)\| + \|f(F_0) - f(F)\| = 2\|f(F_0) - f(F)\| + \|\sigma(g_Q^{-1}(t, F))(f(F_0)) - f(F_0)\|. \quad (6.3.53)$$

The strong continuity of $\sigma(G)$ and the joint continuity of $g_Q$ lead to existence of an open interval $I(F_0, \varepsilon) \subset \mathbb{R}$ containing $t = 0$ as well as of an open neighbourhood of $F_0$, $U(F_0, \varepsilon) \subset K$, corresponding to any $F_0 \in K$ and to any $\varepsilon > 0$, such that

$$\|\sigma(g_Q^{-1}(t, F))(f(F_0)) - f(F_0)\| < \varepsilon/3, \text{ for all } (t; F) \in I(F_0, \varepsilon) \times U(F_0, \varepsilon). \quad (6.3.54)$$

The strong continuity of $\sigma(G)$ leads also to norm continuity of the functions $f_0$ in (6.3.7) which generate $C^G_{bs}$, hence all $f \in C^G_{bs}$ are continuous in norm in the present case. This shows that we can choose the neighbourhoods $U(F_0, \varepsilon)$ in such a way that

$$\|f(F) - f(F_0)\| < \varepsilon/3, \text{ if } F \in U(F_0, \varepsilon), \text{ for any } F_0 \in K. \quad (6.3.55)$$

Since $K$ is compact, we can find a finite set $\{F_p : p = 1, 2, \ldots P\} \subset K$ such that the union of $\{U(F_p, \varepsilon) : p = 1, 2, \ldots P\}$ covers $K$. Let $I(\varepsilon)$ be the intersection of the intervals $\{I(F_p, \varepsilon) : p = 1, 2, \ldots P\}$. Then

$$\|f_t(F) - f(F)\| < \varepsilon, \text{ for all } (t; F) \in I(\varepsilon) \times K. \quad (6.3.56)$$

Taking supremum in (6.3.56) we obtain the desired continuity in (6.3.52). \hfill \Box

**6.3.13.** To compare the derivations $\delta_Q$ from (6.3.43) with $\delta_\pi$ from the formulas (6.2.83), it suffices to take $f \in C^G_{bs}$ where $A^J := A^N$ is a $\sigma(G)$-invariant ‘local algebra’. For such an $f$ we have

$$\sigma(\exp t\xi)(f(F)) = \exp(-itX^N_\xi) f(F) \exp(itX^N_\xi), \quad t \in \mathbb{R}, \quad F \in g^*, \quad (6.3.57)$$

for any $\xi \in g$; here we made the usual identifications, cf. notation in 6.3.10. Then we have

$$\delta_\xi(f(F)) = -i [X^N_\xi, f(F)], \quad (6.3.58)$$

where the commutator is taken between operators in the Hilbert space $p_G H_u$. We can see easily now that the derivations $\delta_\pi$ and $\delta_Q$ are expressed by identical formulas. This proves the identity of the time evolutions determined in Sec.6.2 with the evolutions from the present section in the case of the **UHF-algebra** $A := A^\Pi$ (cf.[53, 2.6.12],[235, 6.4.1]; UHF:="uniformly hyperfinite") with the polynomial $Q$. This shows also that the derivation $\delta_Q$ for the case of a nonseparable $A^\Pi$ and unbounded $X_\xi$ is described by the same formulas as $\delta_\pi$ is.
6.4 Equilibrium states

6.4.1. Let us consider in this section those states of physical systems which describe the situations corresponding to the thermodynamic equilibrium at a given temperature $T \geq 0$. For quantal systems these states are specified usually by the KMS-condition, cf. e.g. \[271, 106, 54, 235\]. We shall investigate here the KMS states of systems considered in this chapter, i.e. the systems specified by the triple $(\mathcal{A}; \sigma(G); \tau^Q)$, cf. also [41]. To avoid possible technical complications, we shall concentrate our attention here on the cases of strongly continuous time evolutions $\tau^Q$ including, e.g. the cases described in 6.3.12(iv). Let us use the notation of Theorem 6.3.12, hence $C := E_\lambda(\mathcal{C}_{bs}^\mathcal{G})$ be the $C^*$-algebra of (generalized) observables describing the considered system with the dynamics $\tau^Q$. Instead of the above mentioned triple, we shall use also the couple $(C; \tau^Q)$ for denoting the system. In most of the analysis of this section an additional structure of the system will be used. Let $\Pi$ be a locally compact noncompact group and $\pi(\Pi)$ be its representation on $C$, i.e. $\pi(p) \in \ast$-Aut $C$ for all $p \in \Pi$. Let $\pi(\Pi)$ commutes with $\tau^Q$:

$$\tau^Q_t \circ \pi(p) = \pi(p) \circ \tau^Q_t \quad \text{for all } t \in \mathbb{R}, \ p \in \Pi. \quad (6.4.1)$$

We shall assume usually that $\pi(\Pi)$ has some asymptotic abelianess properties. As an example of such a $\pi(\Pi)$ consider the situations described in Sec.5.1. (i.e. $\mathcal{A} := \mathcal{A}_{\mathcal{H}}$ is a tensor product of the mutually commuting 'local algebras' $\mathcal{A}_p := \mathcal{L}(\mathcal{H}_p)$, where the set $\mathbb{Z}_+ \setminus \{0\}$ is replaced by $\Pi := \mathbb{Z}^r$ (with easy modifications of the whole formalism). Let us write $\pi_p : \mathcal{L}(\mathcal{H}) \rightarrow \mathcal{L}(\mathcal{H}_\Pi)$ for the isomorphism defined in (5.1.12), $p \in \Pi$. Now we define $\pi(p) \in \ast$-Aut $\mathcal{A}_{\mathcal{H}}$ by

$$\pi(p)(\pi_j(A)) := \pi_{j+p}(A), \quad \text{for all } A \in \mathcal{L}(\mathcal{H}), \ p, \ j \in \Pi. \quad (6.4.2)$$

Since the elements $\pi_j(A) \ (j \in \Pi, \ A \in \mathcal{L}(\mathcal{H}))$ generate $\mathcal{A}_{\mathcal{H}}$, (6.4.2) determines an automorphism $\pi(p)$ of $\mathcal{A}_{\mathcal{H}}$ uniquely. This automorphism can be extended naturally to an (equally denoted) automorphism group $\pi(\Pi)$ of $\mathcal{C} := E_\lambda(\mathcal{C}_{bs}^\mathcal{G})$ by the relation

$$\pi(p)(E_\lambda(f)) := \int \pi(p)(f(F)) E_\lambda(dF). \quad (6.4.3)$$

The group $\pi(\Pi)$ is norm-asymptotically abelian, i.e.

$$\lim_{p \rightarrow \infty} \| [\pi(p)(x), y] \| = 0, \quad \text{for all } x, y \in \mathcal{C}. \quad (6.4.4)$$

In more general cases, the abelianess properties of the action of $\Pi$ on $\mathcal{C}$ can be weaker. Systems with this structure will be denoted

$$(\mathcal{C}; \tau^Q; \pi(\Pi)), \text{ or } (\mathcal{A}; \sigma(G); \tau^Q; \pi(\Pi)).$$

We shall use, as usual, $\beta := T^{-1} := (kT)^{-1}$ to denote the inverse temperature in convenient units. The following definitions are found e.g. in [54, 5.3.1, 5.3.18, and 5.3.21], and [235, 8.12].

\(^3\text{KMS is for Kubo, Martin and Schwinger.}\)
6.4.2 Definition. Let $(\mathcal{C}, \tau)$ be a $C^*$-dynamical system, i.e. the one parameter group $\tau \subset \mathbb{C}^*$-$\text{Aut} \mathcal{C}$ is strongly continuous. The state $\omega \in \mathcal{S}(\mathcal{C})$ is defined to be a $\tau$-KMS state at value $\beta \in \mathbb{R}$, or a $(\tau, \beta)$-KMS state, if

$$\omega(x \tau_{i\beta}(y)) = \omega(y x), \quad \text{for all } x, y \in \mathcal{C}^\circ_{\tau},$$

(6.4.5)

where $\mathcal{C}^\circ_{\tau}$ is a norm-dense, $\tau$-invariant $^*$-subalgebra of the set $\mathcal{C}_\tau$ of the entire analytic elements of $\mathcal{C}$:

$$y \in \mathcal{C}^\circ_{\tau} \iff \text{the function } z \mapsto \tau_z(y) \text{ is analytic for all } z \in \mathbb{C}.$$  

(6.4.6)

Let $\delta_\tau$ be the generator of $\tau$. Then $\omega \in \mathcal{S}(\mathcal{C})$ is called a $\tau$-ground state if

$$-i \omega(y^* \delta_\tau(y)) \geq 0, \quad \text{for all } y \in D(\delta_\tau).$$

(6.4.7)

In this case, $\omega$ is also called a $\tau$-KMS state at value $\beta = \infty$.

6.4.3 Definition. Let $(\mathcal{C}; \tau)$ be a $C^*$-dynamical system with a unital $C^*$-algebra $\mathcal{C}$, and let $\delta_\tau$ be the infinitesimal generator of $\tau$. Then $\omega \in \mathcal{S}(\mathcal{C})$ is said to be a passive state if

$$-i \omega(u^* \delta_\tau(u)) \geq 0$$

(6.4.8)

for any $u \in D(\delta_\tau)$ belonging also to the connected component of the identity of the unitary group of $\mathcal{C}$ in the norm topology.

6.4.4. Let us collect here some important properties of the sets $\mathcal{K}_\beta$ of $(\tau, \beta)$-KMS states:

Proofs of the listed facts can be found in [54, Chap.5], or in [275, 4.3]. We shall consider $\beta \in (0, \infty]$, the set $\mathcal{K}_\infty$ being the set of all ground states $\omega \in \mathcal{S}(\mathcal{C})$. Let $(\mathcal{C}, \tau)$ be a $C^*$-dynamical system. Then:

(0) Any state $\omega \in \mathcal{K}_\beta$ is $\tau$-invariant: $\omega \circ \tau_t = \omega$ ($t \in \mathbb{R}$).

(i) Any $\mathcal{K}_\beta$ is a convex $W^*$-compact subset of $\mathcal{S}(\mathcal{C})$.

(ii-a) For $\beta \neq \infty$, $\mathcal{K}_\beta$ is a simplex in $\mathcal{S}(\mathcal{C})$.

(ii-b) $\mathcal{K}_\infty$ is a face in $\mathcal{S}(\mathcal{C})$.

(iii-a) The set $\mathcal{E}\mathcal{K}_\beta$ of extremal points $\omega \in \mathcal{K}_\beta$ ($\beta \neq \infty$) consists of factor states: The centers of $\pi_\omega(\mathcal{C})''$ are trivial.

(iii-b) The extremal points $\omega \in \mathcal{K}_\infty$, i.e. $\omega \in \mathcal{E}\mathcal{K}_\infty$, are pure states: $\omega \in \mathcal{E}\mathcal{S}(\mathcal{C})$, i.e. $\pi_\omega(\mathcal{C})'' = \mathcal{L}(\mathcal{H}_\omega)$.

(iv) $\omega_j \in \mathcal{E}\mathcal{K}_\beta$ ($\beta \neq \infty, j = 1, 2$) implies either $\omega_1 = \omega_2$, or $\omega_1 \perp \omega_2$, i.e. $\omega_1$ and $\omega_2$ are mutually disjoint, i.e. the central covers $s_{\omega_1}$ and $s_{\omega_2}$ of the corresponding GNS-representations
are mutually orthogonal.

(v) The extremal decomposition of \( \omega \in \mathcal{K}_\beta \) \((\beta \neq \infty)\) coincides with its central decomposition, cf. [53, Chap. 4], [235, Chap. 4]. The corresponding probability measure \( \mu^\omega_\beta \) on \( \mathcal{S}(\mathcal{C}) \) is pseudosupported (cf. [54, Chap. 6]) by \( \mathcal{E}\mathcal{K}_\beta \) and if the Hilbert space of the GNS-representation \( \mathcal{H}_\omega \) is separable, then \( \mu^\omega_\beta \) is supported by \( \mathcal{E}\mathcal{K}_\beta : \mu^\omega_\beta(\mathcal{E}\mathcal{K}_\beta) = \mu^\omega_\beta(\mathcal{S}(\mathcal{C})) = 1 \).

**6.4.5 Lemma.** Let \( \omega \in \mathcal{S}(\mathcal{C}) \) be a \( \tau \)-ground state. Let \( (\pi_\omega, \mathcal{H}_\omega, \Omega_\omega) \) be the corresponding GNS representation. Then for the unique selfadjoint operator \( Q_\omega \) on \( \mathcal{H}_\omega \) determined by the relation:

\[
\exp(it \, Q_\omega) \pi_\omega(y) \Omega_\omega := \pi_\omega(\tau_t(y)) \Omega_\omega, \quad \forall t \in \mathbb{R},
\]

the following is valid:

\[
Q_\omega \geq 0, \quad \text{and for all } t \in \mathbb{R} \text{ one has } \exp(it \, Q_\omega) \in \pi_\omega(\mathcal{C})''.
\]

**Proof.** See [54, 5.3.19]. \( \square \)

**6.4.6.** Any \((\tau, \beta)\)-KMS state, according to 6.4.4(i), can be approximated in the \( w^\ast \)-topology by convex combinations of extremal KMS states at the same temperature \( \beta^{-1} \). The set \( \mathcal{K}_\beta \) may be void for a general dynamical system and for a given \( \beta \in (0, \infty) \). Occurrence of more than one points in \( \mathcal{K}_\beta \) means occurrence of several mutually disjoint states in \( \mathcal{E}\mathcal{K}_\beta \). Orthogonal central projectors \( s_1 \) and \( s_2 \) (the central covers of the corresponding GNS representations) are supporting such disjoint states; these \( s_j \in \mathfrak{I} := \text{the center of } \pi_a(\mathcal{C})'' \) may be interpreted as corresponding to distinct values of a macroscopic (global, classical) quantity for distinct \( j = 1, 2 \). We interpret this situation as possibility of existence of several mutually different 'phases' of the considered system at the temperature \( T = \beta^{-1} \). This interpretation is especially intuitive in cases of quasilocal algebras \( \mathcal{C} \) when the extremal KMS (hence factor) states have short range correlations (cf. e.g. [193]) - the necessary property of the states representing pure phases of a spatially extended system [271, 6.5]. We shall investigate general properties of the extremal \((\tau^Q, \beta)\)-KMS states of the systems \( (\mathcal{C}; \tau^Q) \) and \( (\mathcal{C}; \tau^Q; \pi(\Pi)) \) representing the generalized mean-field theories.

**6.4.7 Proposition.** Let \( \omega \in \mathcal{K}_\beta \) be an extremal \( \tau^Q \)-KMS state of a generalized mean-field theory \( (\mathfrak{A}; \sigma(G); \tau^Q) \). Then there is an element \( F_\omega \in \text{supp } E_\theta \) such that the central support \( s_\omega \leq E_\theta(B) \) for any open \( B \subset \mathfrak{g}^* \) containing \( F_\omega : F_\omega \in B \). The point \( F_\omega \) is a fixed point of the classical flow \( \varphi^Q \) on \( \mathfrak{g}^* \). The state \( \omega \) is invariant with respect to the one parameter subgroup of \( \sigma(G) \) generated by the element \( \beta^Q_{F_\omega} \in \mathfrak{g} \), (6.1.17), and the generator \( Q_\omega \) of \( \tau^Q \) in \( \pi_\omega(\mathfrak{A}) \) implements this subgroup in the sense that

\[
\pi_\omega \left( \sigma(\exp(-\beta^Q_{F_\omega} t))(x) \right) \Omega_\omega = \exp(it \, Q_\omega) \pi_\omega(x) \Omega_\omega, \quad t \in \mathbb{R}, \quad x \in \mathfrak{A}.
\]

The image \( \pi_\omega(\mathcal{C}) \) of \( \mathcal{C} := E_\theta(\mathcal{C}_{bs}^G) \) coincides with \( \pi_\omega(\mathfrak{A}) \), \( \mathfrak{A} = E_\theta(\mathfrak{A}) \) (\( \mathfrak{A} \subset \mathcal{C}_{bs}^G \) represents here \( \mathfrak{A} \)-valued constant functions).
6.4. EQUILIBRIUM STATES

Assume that the whole group $\sigma(G)$ is unitarily implemented in the representation $(\pi_\omega, \mathcal{H}_\omega, \Omega_\omega)$. Then we can choose the generators $X_\omega(\xi)$ of the one parameter subgroups $\exp(t\xi)$ in such a way that

$$Q_\omega = X_\omega(\beta^Q_{F_\omega}) = \sum_{j=1}^{n} \partial_j Q(F_\omega) X_\omega(\xi_j)$$  \hspace{1cm} (6.4.12)

for any basis $\{\xi_j : j = 1, 2, \ldots n\}$ in $\mathfrak{g}$.

Proof. The factor state $\omega$ is projected by $p_M$ onto a pure state on $\mathfrak{M}_G$, 5.1.35, hence the decomposition of $\omega$ in (6.3.16) is concentrated on a one point set $F_\omega \subset \text{supp } \mathcal{E}_\omega$. Let $f_j (j = 1,2)$ be any such elements of $\mathfrak{c}^*_{\text{fin}}$ that $f_1 (F_\omega) = f_2 (F_\omega)$. Then

$$\omega(\mathcal{E}_\omega(f_1)) = \omega(\mathcal{E}_\omega(f_2)) = \omega(f_1(F_\omega)) = \omega(f_2(F_\omega)).$$  \hspace{1cm} (6.4.13)

This proves that $\pi_\omega(\mathfrak{c}) = \pi_\omega(\mathfrak{a})$. The state $\omega \circ \tau^Q_1 \equiv \omega$ is then concentrated (in the above described sense) on $\varphi^Q_1(F_\omega)$, and states $\omega_1$ and $\omega_2$ concentrated on $F_1 \neq F_2$ are disjoint: $\omega_1 \perp \omega_2$. Hence, $\varphi^Q_1(F_\omega) = F_\omega$ for all $t \in \mathbb{R}$. This means, however, that the classical Poisson bracket \{Q, f\}(F_\omega) = 0 for any function $f$. It follows that for the generator $\delta_Q$, (6.3.43), in the representation $\pi_\omega$, one has:

$$\omega(x\delta_Q(\mathcal{E}_\omega(f)))y = -\sum_{j=1}^{n} \partial_j Q(F_\omega) \omega(x\partial_j(\mathcal{E}_\omega(f)))y, \ x, y \in \mathfrak{a}.$$  \hspace{1cm} (6.4.14)

The definition of the time evolution in 6.3.8 and the $\varphi^Q$-invariance of $F_\omega$ shows the identity of the time evolution of $\pi_\omega(\mathfrak{a})$ with the action of the one-parameter group $g^{-1}_Q(t, F_\omega)$, cf. (6.1.13), with the generator $-\beta^Q_{F_\omega}$, cf. (6.1.10). According to (6.1.17) and (6.1.18) we obtain the remaining assertions of the proposition.

6.4.8 Note. The generator of the mean-field time evolution $\tau^Q$ of local perturbations of an extremal equilibrium state $\omega$ given in (6.4.12) is usually called the Bogoliubov–Haag Hamiltonian, cf. [23, 140, 312].

6.4.9. We shall assume in the following that $\mathfrak{a}$ is a quasilocal $C^*$-algebra generated by a net $\{\mathfrak{a}^J : J \subset \Pi, J \text{ finite}\}$ of local subalgebras $\mathfrak{a}^J$ commuting with each other for disjoint $J$’s:

$$x \in \mathfrak{a}^J, \ y \in \mathfrak{a}^{J'}, \ J \cap J' = \emptyset \Rightarrow [x, y] = 0.$$  \hspace{1cm} (6.4.15)

Here $\Pi$ is a countable infinite commutative group acting on $\mathfrak{a}$ by the representation $\pi : \pi_\rho \in ^*\text{Aut } \mathfrak{a}$, in such a way that $\pi_\rho : \mathfrak{a}^J \to \mathfrak{a}^{J+p}$ is an isomorphism for any $J \subset \Pi$. This is the situation from (6.4.2), where $\mathcal{L}(\mathcal{H})$ is identified with $\mathcal{L}(\mathcal{H}_0)$, $\pi_0 = \pi(0) = \text{id}_{\mathcal{L}(\mathfrak{a})}$ (0 is here the identity of the group $\Pi$), hence $\pi(\rho) = \pi_\rho (\rho \in \Pi)$.

It will be assumed in the following that each $\mathfrak{a}^J (J \subset \Pi)$ is $\sigma(G)$-invariant, and that the action of $\sigma(G)$ commutes with $\pi(\Pi)$. Then also (6.4.1) will be fulfilled ($\pi(\Pi)$ is naturally extended to the equally denoted automorphism groups of $\mathfrak{c}$ and of $\mathfrak{a}^{**}$).
In this situation, let \( \omega \in \mathcal{S}(\mathfrak{A}) \) be a factor state which is invariant with respect to the action of \( \pi(\Pi) \):
\[
\omega(\pi_p(x)) = \omega(x), \text{ for all } x \in \mathfrak{A}, \ p \in \Pi. \tag{6.4.16}
\]

The locally normal factor states have short range correlations, [193], [53, Thm.2.6.10], hence they are weakly \( \pi(\Pi) \)-clustering, and
\[
\lim_{p \to \infty} \omega(\pi_p(x)y) = \omega(x)\omega(y), \text{ for all } x, y \in \mathfrak{A}. \tag{6.4.17}
\]

If \( \mathfrak{A}^J \) are faithfully represented in Hilbert spaces \( \mathcal{H}_J \), as it was the case of Sec.5.1, then \( \pi_p \) will be used also for translations of unbounded operators acting on \( \mathcal{H}_J \) to unitarily equivalent operators acting on \( \mathcal{H}_{J+p} \) (e.g. by translating their spectral projectors belonging to \( \mathfrak{A}^J \)); this can be done if the isomorphisms of \( \mathfrak{A}^J \subset \mathcal{L}(\mathcal{H}_J) \) with \( \mathfrak{A}^{J+p} \subset \mathcal{L}(\mathcal{H}_{J+p}) \) (\( J < \Pi, \ p \in \Pi \)) are spatial. We shall write also \( \mathfrak{A}_p := \mathfrak{A}^J \) with \( J := \{p\} := \) the one-point set, \( p \in \Pi \). Let all the \( \mathfrak{A}^J \) (\( J \subset \Pi \)) have common unit and let the \( \mathfrak{C}^* \)-algebras \( \mathfrak{A}_p \) with \( p \in J \) generate \( \mathfrak{A}^J \) (\( J \subset \Pi \)).

With the introduced notation and assumptions, we shall prove now the following:

**6.4.10 Theorem.** Let us consider a system \( (\mathfrak{A}; \sigma(G); \tau^Q; \pi(\Pi)) \) with simple \( \mathfrak{C}^* \)-algebra \( \mathfrak{A} \) and ‘local’ subalgebras \( \mathfrak{A}^J \subset \mathfrak{A} \) being factors for all finite \( J \). Let \( \omega \in \mathcal{S}(\mathfrak{A}) \) and let \( \omega^0 \) be the restriction of \( \omega \) to the subalgebra \( \mathfrak{A}_0 \) (:= \( \mathfrak{A}^J \) with the one-point set \( J \) containing the identity \( 0 \in \Pi \)). Then the following two statements are equivalent:

(i) \( \omega \) is a locally normal extremal \( \tau^Q \)-KMS state at a positive temperature \( \beta^{-1} > 0 \).

(ii) \( \omega = \overline{\omega} \), where \( \overline{\omega} \) is the \( \pi(\Pi) \)-invariant product state determined by the relation
\[
\overline{\omega}(\pi_{p_1}(x_1)\pi_{p_2}(x_2)\ldots\pi_{p_m}(x_m)) = \prod_{j=1}^{m} \omega^0(x_j), \tag{6.4.18}
\]
with \( x_j \in \mathfrak{A}_0, \ p_j \in \Pi \) (\( p_j \neq p_k \) for \( j \neq k \)), \( j = 1, 2, \ldots, m \), \( \forall m \in \mathbb{N} \) and \( \omega^0 \) is the faithful normal KMS-state at \( \beta \) on \( \mathfrak{A}_0 \) corresponding to the one-parameter subgroup \( \{\sigma(exp(-t\beta^Q_{F_{\xi}})) : t \in \mathbb{R}\} \) of \( \mathfrak{C}^*-\text{Aut} \mathfrak{A}_0 \) with
\[
\varphi^Q_t(F_\omega) = F_\omega, \text{ for all } t \in \mathbb{R} \tag{6.4.19}
\]
for some element \( F_\omega \in \mathfrak{g}^* \). Moreover, the ‘consistency condition’
\[
\omega(E_{\mathfrak{g}}(f_{\xi})) = F_\omega(\xi), \quad (\xi \in \mathfrak{g}, \ f_{\xi}(F) := F(\xi) \text{ for } F \in \mathfrak{g}^*) \tag{6.4.20}
\]
is fulfilled.\(^4\)

**Proof.** (i) implies \( \pi_\omega(\tau^Q_t(x)) = \pi_\omega(\sigma(exp(-t\beta^Q_{F_{\xi}}))(x)) \) according to (6.4.11). Hence \( \omega \) satisfies the KMS-condition with respect to the group \( \sigma(exp(-t\beta^Q_{F_{\xi}})) \) at \( T^{-1} \) and the same is true for \( \omega^0 \), since \( \sigma(G)(\mathfrak{A}_0) = \mathfrak{A}_0 \). Let \( X(\beta^Q_{F_{\xi}}) \) be the restriction of \( X_\omega(\beta^Q_{F_{\xi}}) \) onto \( \overline{\pi_\omega(\mathfrak{A}_0)}\Omega_\omega \). \( \omega \) is faithful

\(^4\)The stationarity (6.4.19) is a consequence of the “consistency condition” (6.4.29), i.e. of (6.4.20); hence (6.4.19) & (6.4.20) can be replaced by (6.4.29).
on \( \mathfrak{A} \) (\( \mathfrak{A} \) is simple) and the cyclic vector \( \Omega_\omega \) is separating for \( \pi_\omega(\mathfrak{A})'' \), cf. [54, 5.3.9]. Hence \( \omega(x^*x) \neq 0 \) for \( x \neq 0 \), and \( \omega \) is faithful on \( \mathfrak{A}_0 \). The local normality of \( \omega \) implies normality of \( \omega^0 \). According to the Takesaki’s theorem [54, 5.3.10], the one-parameter automorphism group of \( \pi_\omega(\mathfrak{A}_0) \):

\[
t \mapsto \exp(itX(\beta_{\omega}^0))\pi_\omega(x) \exp(-itX(\beta_{\omega}^0)), \quad x \in \mathfrak{A}_0,
\]

(6.4.21) coincides with the corresponding modular automorphism group of \( \pi_\omega(\mathfrak{A}_0) \) determined by the state \( \omega^0 \) (up to a rescaling of time \( t \)). According to [54, 5.3.29], the KMS state at \( \beta := T^{-1} \in \mathbb{R} \) on the factor \( \mathfrak{A}_0 \) corresponding to its automorphism group \( \sigma(\exp(-t\beta_{\omega}^0)) \) is uniquely determined faithful normal state on \( \mathfrak{A}_0 \).

We have to prove that \( \omega \) is a \( \pi(\Pi) \)-invariant product state on \( \mathfrak{A} \), i.e. that (6.4.18) (with \( \omega \mapsto \overline{\omega} \)) is satisfied. Let \( y := \pi_p(x) \) for some \( x \in \mathfrak{A}_0, \ p \in \Pi \). From the commutativity of \( \pi(\Pi) \) with \( \sigma(G) \) we have for \( y' := \pi_p(x') \):

\[
\omega(\tau_t^Q(y)y') = \omega \circ \pi_p(\tau_t^Q(x)x'), \text{ for all } x, x' \in \mathfrak{A}_0, \ t \in \mathbb{R}.
\]

(6.4.22) We can write here \( \omega^p \in \mathcal{S}(\mathfrak{A}_p) \) instead of \( \omega \). The state \( \omega^p \) is a KMS-state, hence \( \omega^p \circ \pi_p \in \mathcal{S}(\mathfrak{A}_0) \) is the unique KMS state \( \omega^0 \):

\[
\omega^p \circ \pi_p = \omega^0, \text{ for all } p \in \Pi.
\]

(6.4.23) Since all the \( \mathfrak{A}^J \) are factors (\( J \) finite), we can repeat the above considerations for the restrictions \( \omega^J \) of \( \omega \) to \( \mathfrak{A}^J \) (with \( J \) replacing the one point set \( \{0\} \subset \Pi \)): \( \omega^J \) is the unique KMS state at \( T^{-1} \) of \( \mathfrak{A}^J \) corresponding to the group \( \sigma(\exp(-t\beta_{\omega}^Q)) \in \ast\text{-Aut } \mathfrak{A}^J \), and

\[
\omega^{J+p} \circ \pi_p = \omega^J \text{ for all finite } J \subset \Pi, \ p \in \Pi.
\]

(6.4.24) For an arbitrary local element \( x \in \mathfrak{A}^J \) one obtains:

\[
\omega \circ \pi_p(x) = \omega^{J+p} \circ \pi_p(x) = \omega^J(x) = \omega(x),
\]

(6.4.25) hence we have the translation invariance \( \omega \circ \pi_p = \omega \) of the extremal \( \tau^Q \)-KMS state \( \omega \) at positive temperature \( T \).

The restriction to \( \mathfrak{A}^J \) of the product state \( \overline{\omega} \) in the right hand side of (6.4.18) satisfies the KMS condition at \( T^{-1} \) with respect to the one parameter group \( \{\sigma(\exp(-t\beta_{\omega}^Q)) : t \in \mathbb{R}\} \subset \ast\text{-Aut } \mathfrak{A}^J \), since for all \( x_j, y_j \in \mathfrak{A}_0, \ j = 1, 2, \ldots m, \) one has the identity

\[
\overline{\omega}(\pi_{p_1}(x_1)\pi_{p_2}(x_2)\ldots\pi_{p_m}(x_m)\tau_1(\pi_{p_1}(y_1)\pi_{p_2}(y_2)\ldots\pi_{p_m}(y_m))) = \\
\overline{\omega}(\pi_{p_1}(x_1\tau_1(y_1))\pi_{p_2}(x_2\tau_1(y_2))\ldots\pi_{p_m}(x_m\tau_1(y_m))) = \\
\Pi_{j=1}^m \omega^0(x_j\tau_1(y_j)), \text{ for all } m\text{-tuples } \{p_1, p_2, \ldots p_m\} \subset \Pi, \ m = 1, 2, \ldots ,
\]

(6.4.26) where \( \tau_1 \in \ast\text{-Aut } \mathfrak{A} \) leaves all \( \mathfrak{A}^J \) invariant: \( \tau_1(\mathfrak{A}^J) = \mathfrak{A}^J, \ J \subset \Pi \). Setting \( \tau_1 := \sigma(\exp(-t\beta_{\omega}^Q)) \), we obtain the KMS-property of \( \overline{\omega} \) from the proved KMS-property of the state \( \omega^0 \), since the finite linear combinations of the products

\[
\pi_{p_1}(x_1)\pi_{p_2}(x_2)\ldots\pi_{p_m}(x_m), \ x_j \in \mathfrak{A}_0, \ p_j \in \Pi, \ m \in \mathbb{Z}_+ \setminus \{0\},
\]

(6.4.27)
form such a subset \( \mathfrak{A}_L^0 \) of \( \mathfrak{A} \), that the values
\[
\varpi(y) \in \mathbb{C}, \ y \in \mathfrak{A}_L^0,
\] (6.4.28)
determine any locally normal state \( \varpi \in \mathcal{S}(\mathfrak{A}) \) uniquely. The uniqueness of the KMS-states on \( \mathfrak{A}^J \) (\( J \) finite) gives the restrictions of \( \omega \) to all the \( \mathfrak{A}^J \), hence we have equality \( \varpi = \omega \) of the states on \( \mathfrak{A} \), hence the relation (6.4.18). [Warning: This does not imply uniqueness of the \( \tau^Q \)-KMS states on \( \mathcal{C} \), but we have proved uniqueness of the KMS states on \( \mathcal{C} \) with respect to one parameter groups \( \sigma(\exp(t\xi)) := \sigma_\xi(t) \). Different extremal \( \tau^Q \)-KMS states at the same temperature \( T \) give different values of \( F_\omega \) and of \( \beta^Q_{F_\omega} \), hence lead to different one parameter groups \( \sigma_\xi (\xi := -\beta^Q_{F_\omega}) \).]

Let now \( \omega^0 \in \mathcal{S}(\mathfrak{A}_0) \) be a given faithful normal KMS-state at the temperature \( T > 0 \) corresponding to the group \( \sigma_\xi \) with \( \xi := -\beta^Q_{F_\omega} \), where \( F_\omega \in \mathfrak{g}^* \) satisfies (6.4.19). Then the product state \( \varpi \) from (6.4.18) is locally normal, since the finite product of normal states is a normal state on the tensor product of \( W^* \)-algebras, [306, Sec.IV.5]. The factoriality is trivial for product states, [53, 2.6.10]. According to the Pusz-Woronowicz theorem, [54, 5.3.22], \( \omega^0 \) satisfies the passivity condition (6.4.8) with \( \tau := \sigma_\xi (\xi := -\beta^Q_{F_\omega}) \). This implies the satisfaction of (6.4.8) with respect to the same group by the state \( \varpi \). The cluster property of the product state gives now the KMS-property of \( \varpi \) with respect to the \( \sigma_\xi \). Since \( \omega^0 \) satisfies \( \sigma_\xi \)-KMS condition with \( T \neq 0 \) positive, the same is true for \( \varpi \). Since \( F_\omega \) is a fixed point of \( \varphi^Q \), the derivations of the \( \sigma_\xi \) and of \( \tau^Q \) coincide in the GNS-representations corresponding to the states supported by \( E_\varphi(F_\omega) \), cf. (6.4.14). The assumption (6.4.20) ensures, that the macroscopic limit of the product state \( \varpi \) from (6.4.18) is concentrated on \( F_\omega \), hence the evolutions \( \tau^Q \) and \( \sigma_\xi (\xi := -\beta^Q_{F_\omega}) \) coincide in the representation \( \pi_\omega \) corresponding to the state \( \omega := \varpi \) from (6.4.18).

**6.4.11 Corollary.** Let \( \mathfrak{A} := \mathfrak{A}^\Pi \) and the system \( (\mathfrak{A}; \sigma(G); \pi(\Pi)) \) be defined according to Sec.5.1, i.e. the G-measure \( E_\varphi \) is given by 5.1.33 and \( \sigma(G) \) is locally implementable in states \( \omega \in \mathcal{S}_0 \).

Let, with the assumptions of Theorem 6.4.10, \( \omega \) be locally normal extremal \( \tau^Q \)-KMS state at \( T > 0 \). Let \( X_\xi (\xi \in \mathfrak{g}) \) be the generators of the \( \sigma(G) \)-defining representation \( U(G) \) on \( \mathcal{H}_0 := \mathcal{H}, \ \mathfrak{A}_0 = \mathcal{L}(\mathcal{H}) \), \( \sigma(\exp(t\xi))(y) := \exp(-itX_\xi)y\exp(itX_\xi) \) for all \( y \in \mathfrak{A}_0 \). Then
\[
\omega^0(\exp(itX_\xi)) = \exp(itF_\omega(\xi)), \ \forall \xi \in \mathfrak{g},
\] (6.4.29)
where \( F_\omega \) is given by the (trivially fulfilled) ‘consistency condition’
\[
\omega(E_\varphi(f_\xi)) = F_\omega(\xi), \ \xi \in \mathfrak{g}.
\] (6.4.30)

**Proof.** Since \( \exp(itX_\xi) \in \mathfrak{A}_0 \), the generators of the restriction of \( \sigma(G) \) onto \( \mathfrak{A}_p := \pi_p(\mathfrak{A}_0) \) are \( \pi_p(X_\xi) \), where
\[
\exp(it\pi_p(X_\xi)) := \pi_p(\exp(itX_\xi)).
\] (6.4.31)
The generators of the restriction of \( \sigma(G) \) onto \( \mathfrak{A}^J \) (finite \( J \subset \Pi \)) are \( X^J_\xi := \sum_{\xi \in J} \pi_p(X_\xi) \),
\[
\exp(itX^J_\xi) := \prod_{\xi \in J} \exp(it\pi_p(X_\xi)) \in \mathfrak{A}^J.
\] (6.4.32)
\( \omega \) is expressed by (6.4.18), hence according to (5.1.120):

\[
\exp(itF_\omega(\xi)) = \omega(\exp(itX_{\Xi})) = \lim_J \omega(\exp\left(\frac{it}{|J|} X^J_\xi\right)) = \lim_J \prod_{\ell \in J} \omega^0(\exp\left(\frac{it}{|J|} X_\xi\right)) = \lim_{|J| \to \infty} [\omega^0(\exp\left(\frac{it}{|J|} X_\xi\right))]^{\mid J \mid}. \tag{6.4.33}
\]

The result (6.4.29) is now obtained from (6.4.33) by the ‘law of large numbers’ ([112, II.Ch.XVII.1.Thm.1]) applied to the arithmetic means of \(|J|\) copies of independent real-valued variables with equal distributions \(\mu^0_\xi\). The probability measure \(\mu^0_\xi\) on \(\mathbb{R}\) is given here by the projection-valued spectral measure \(P_\xi\) of \(X_\xi\):

\[
X_\xi = \int_{\mathbb{R}} \lambda P_\xi(d\lambda). \tag{6.4.34}
\]

Then we set

\[
\mu^0_\xi(d\lambda) := \omega^0(P_\xi(d\lambda)), \tag{6.4.35}
\]

and we can write:

\[
[\omega^0(\exp\left(\frac{it}{|J|} X_\xi\right))]^{\mid J \mid} = \int_{\mathbb{R}^{\mid J \mid}} \exp\left(\frac{it}{|J|} \sum_{\ell \in J} \lambda_\ell\right) \otimes_{m \in J} \mu^0_\xi(d\lambda_m), \tag{6.4.36}
\]

where \(\otimes_{m \in J} \mu^0_\xi(d\lambda_m)\) is the tensor product of \(|J|\) copies of the measures (6.4.35) describing the simultaneous probability distribution of the \(|J|\) independent random variables. Combining (6.4.33) and (6.4.36) gives the wanted result (6.4.29).

6.4.12 Proposition. Let us consider the system \((\mathfrak{A}; \sigma(G); \tau^Q; \pi(\Pi))\) as in Theorem 6.4.10. Assume that \(\omega^p (p \in \Pi)\) are ground states for the restriction of the group \(\sigma(\exp(-t\beta^Q_F))\) to the subalgebras \(\mathfrak{A}_p\). Let the product-state

\[
\omega := \bigotimes_{p \in \Pi} \omega^p \tag{6.4.37}
\]

satisfy the ‘consistency condition’

\[
\omega(E_\xi(f_\xi)) = F_\omega(\xi), \text{ for all } \xi \in \mathfrak{g}. \tag{6.4.38}
\]

Then \(\omega\) is a factor ground state of the evolution \(\tau^Q\). If all the \(\omega^p\) are pure, then \(\omega\) is an extremal \(\tau^Q\)-ground state.

Proof. The factoriality of \(\omega\) is a consequence of cluster properties, cf. e.g. [53, 54]. The condition (6.4.7) is fulfilled for \(\tau_t := \sigma(\exp(-\beta^Q_F t))\). An application of Proposition 6.4.7 shows the fulfillment of the ground state condition also for \(\tau := \tau^Q\). The validity of the remaining assertions is clear.

6.4.13 Note. A brief version of the here presented theory together with applications to models of BCS theory and of Josephson junction was published in [40, 41]. Cf. also the next section.
6.5 An example: The B.C.S. model of superconductivity

6.5.1. We shall illustrate in this section the above developed theory by description and analysis of a perhaps simplest nontrivial and physically interesting mathematical model: The strong coupling version of the Bardeen-Cooper-Schrieffer model of the phenomenon of superconductivity in the quasi spin formulation; it was formulated and analyzed in [312, 311, 168], in the framework of the traditional QM formalism. It can be presented, completed, and solved in the framework of the constructions of the present work as follows:

It is a tensor product type model of Sec.5.1 with \( G = SU(2), \) \( \mathcal{H} = \mathcal{H}_0 = \mathbb{C}^2, \) \( \Pi = \mathbb{Z}, \) the generators of \( U(G) \) in \( \mathbb{C}^2 \) are

\[ X_{\xi_j} := i \frac{d}{dt} \bigg|_{t=0} U(\exp(t\xi_j)) = \frac{1}{2}\sigma_j, \quad j = 1, 2, 3, \quad (6.5.1) \]

where \( \sigma_j \) are the Pauli matrices and the elements \( \xi_j \in \mathfrak{g} \) of the chosen basis satisfy the relations

\[ [\xi_j, \xi_k] = \varepsilon_{jkm}\xi_m, \quad j, k, (m) = 1, 2, 3. \quad (6.5.2) \]

Let \( F_j := F(\xi_j) \) be used for the functions \( f_{\xi_j} \) on \( \mathfrak{g}^* \ni F \) as well as for their numerical values in the points \( F \in \mathfrak{g}^* \). The dynamics of the system is specified by the function \( Q \) on \( \mathfrak{g}^* \):

\[ Q(F) = -2\varepsilon F_3 - \lambda(F_1^2 + F_2^2), \quad \varepsilon, \lambda \text{ are some positive numbers.} \quad (6.5.3) \]

This specifies the model completely.

6.5.2. The Poisson structure on \( \mathfrak{g}^* = su(2)^* \) is determined by the Poisson brackets

\[ \{F_j, F_k\} = -\varepsilon_{jkm}F_m, \quad j, k, (m) = 1, 2, 3, \quad (6.5.4) \]

which are obtained from (6.5.2) according to (5.1.145). The classical dynamics corresponding to the given Hamiltonian function \( Q \in C^\infty(su(2)^*, \mathbb{R}) \) is then described by the flow \( \varphi^Q \) on \( su(2)^* \) which is determined by the Hamilton equations

\[ \dot{F}_j(\varphi^Q_t F) := \frac{d}{dt}F_j(\varphi^Q_t F) = \{Q, F_j\}(\varphi^Q_t F), \quad t \in \mathbb{R}, \quad j = 1, 2, 3. \quad (6.5.5) \]

We see from (6.5.4) that \( \varphi^Q \) is nontrivial for a general \( Q \), hence the symplectic (even dimensional) \( Ad^* \)-orbits in \( su(2)^* \) (which is 3-dimensional) are two-dimensional (with the exception of a zero-dimensional orbit consisting of the point \( F = 0 \)). Since \( SU(2) \) is a compact group, orbits are compact orientable two-dimensional manifolds in \( su(2)^* \). They are submanifolds of the spheres \( S^2_r \):

\[ F^2 := F_1^2 + F_2^2 + F_3^2 = r^2, \quad (6.5.6) \]

because

\[ \{F^2, F_j\} = 0 \text{ for } j = 1, 2, 3. \quad (6.5.7) \]
Hence the $\text{Ad}^*(\mathfrak{su}(2))$-orbits are the spheres $S^2_r$. The equations of motion with $Q$ from (6.5.3) are

$$\dot{F}_j = \{Q, F_j\} = -2\varepsilon\{F_3, F_j\} - 2\lambda(F_1\{F_1, F_j\} + F_2\{F_2, F_j\}),$$

that is

$$\dot{F}_1 = 2(\varepsilon - \lambda F_3)F_2,$$ \hspace{1cm} (6.5.9a)

$$\dot{F}_2 = -2(\varepsilon - \lambda F_3)F_1,$$ \hspace{1cm} (6.5.9b)

$$\dot{F}_3 = 0.$$ \hspace{1cm} (6.5.9c)

The solution is elementary: With

$$F_\pm := F_1 \pm iF_2,$$ \hspace{1cm} (6.5.10)

one has the flow $\varphi^Q$ determined by the equations

$$F_3(t) = F_3 \equiv F_3(0), \hspace{1cm} t \in \mathbb{R},$$ \hspace{1cm} (6.5.11a)

$$F_+(t) = F_+(0) \exp(-i2(\varepsilon - \lambda F_3) t).$$ \hspace{1cm} (6.5.11b)

We shall assume $\lambda \neq 0$. The set of all stationary points $F \in \mathfrak{su}(2)^*$ of the flow $\varphi^Q$ consists of points satisfying the conditions:

Either

$$F_+ = 0, \hspace{1cm} \text{and} \hspace{1cm} F_3 = \text{arbitrary real number},$$ \hspace{1cm} (6.5.12a)

or

$$F_3 = \frac{\varepsilon}{\lambda}, \hspace{1cm} \text{and} \hspace{1cm} F_+ = \text{arbitrary complex number}.$$ \hspace{1cm} (6.5.12b)

The ‘physical region’ for the values $F$ of the considered quantum mechanical system consists, however, of the points $F \in \text{supp } E_g \subset \mathfrak{su}(2)^*$. 

**6.5.3 Lemma.** $\text{supp } E_g = \{F \in \mathfrak{su}(2)^*: F^2 \leq \frac{1}{4}\}$.

*Proof.* The spectra of the generators $X_\xi_j$ ($j = 1, 2, 3$) are the two-point sets $\{\lambda = \pm \frac{1}{2}\}$. According to the proof of Lemma 6.2.17, $\text{supp } E_g = \{F \in \mathfrak{g}^*: F(\xi) \in \text{conv } sp(X_\xi) \hspace{1cm} \forall \xi \in \mathfrak{g}\}$. Since $\text{supp } E_g$ is $\text{Ad}^*$-invariant and the $\text{Ad}^*$-orbits are spheres $S^2_r$, the set $\text{supp } E_g$ is the ball $\{F: F \in S^2_r, 0 \leq r \leq \frac{1}{2}\}$. \hfill \Box

**6.5.4.** The quantum evolution $\tau^Q$ is determined according to 6.3.8 and 6.3.11 by $\varphi^Q$ as well as by the cocycle $\sigma(g_Q^{-1}(t, F)) \in *$-$\text{Aut } \mathfrak{A}$, where $\mathfrak{A}$ is the quasilocal algebra of our spin system. The action of this cocycle on the local algebra $\mathfrak{A}_0$ ($:= \text{the algebra of the } \frac{1}{2}\text{-spin sitting at the site } 0 \in \Pi$) is given by the unitary family $U(g_Q(t, F))$ satisfying the Schrödinger-type evolution equation
\[ i \frac{d}{dt} U(g_Q(t, F)) = X(\beta^Q_F)U(g_Q(t, F)), \ F(t) := \varphi^Q_t(F), \]  
(6.5.13)
as can be seen from (6.1.16). The elements \( \beta^Q_F \in su(2) \) are defined by (6.1.17), i.e.
\[ \beta^Q_F := d_F Q = -2\varepsilon\xi_3 - 2\lambda(F_1\xi_1 + F_2\xi_2). \]  
(6.5.14)

In the representation \( g \mapsto U(g) \) one has
\[ X(\beta^Q_F) = -\varepsilon\sigma_3 - \lambda(F_1\sigma_1 + F_2\sigma_2) = -a(F) \mathbf{n}(F) \cdot \mathbf{\sigma}, \]  
(6.5.15)
where \( \mathbf{\sigma} := \{\sigma_1, \sigma_2, \sigma_3\} \) is the 3-vector of \( \sigma \)-matrices,
\[ a(F) := \sqrt{\varepsilon^2 + \lambda^2 F_+ F_-}, \]  
(6.5.16)
and \( \mathbf{n}(F) := \{n_1, n_2, n_3\} \) with
\[ n_1 := \frac{\lambda F_1}{a(F)}, \ n_2 := \frac{\lambda F_2}{a(F)}, \ n_3 := \frac{\varepsilon}{a(F)}, \]  
(6.5.17)
and \( \mathbf{n} \cdot \mathbf{\sigma} := n_j\sigma_j \) is the scalar product.

If \( F \in su(2)^* \) is one of the stationary points (6.5.12), then the function \( t \mapsto g_Q(t, F) \) will be a one-parameter subgroup of \( SU(2) \) with the generator \( \beta^Q_F \). This subgroup is the stability subgroup of \( F \) with respect to the \( Ad^*(SU(2)) \)-representation (for \( F \neq 0 \)). The time evolution \( \tau^Q \) in those states \( \omega \) the classical projection of which is concentrated on \( F_\omega = F \) is now identical with the evolution according to the subgroup of \( \sigma(SU(2)) \) specified by the element \( \beta^Q_F \in \mathfrak{g} \). The generator \( Q_\omega \) of this evolution in the representation \( \pi_\omega \) can be expressed by its commutators with \( \pi_\omega(y), y \in \mathfrak{A}^J \) (finite \( J \subset \Pi \)):
\[ [Q_\omega, \pi_\omega(y)] = [\pi_\omega(X^J(\beta^Q_F)), \pi_\omega(y)] \text{ for } y \in \mathfrak{A}^J, \ J := \{p_1, \ldots p_m\}, \]  
(6.5.18)
where the usual notation \( X^J(\xi) := \sum_{p \in J} \pi_p(X(\xi)) \) was used, cf. (6.4.12). The generator \( Q_\omega \) is a well defined selfadjoint operator on the space \( \mathcal{H}_\omega \) of the representation \( \pi_\omega \) chosen so that \( Q_\omega \Omega_\omega = 0 \) on the cyclic vector \( \Omega_\omega \). This is the meaning of the Bogoliubov-Haag Hamiltonian operator \( Q_\omega \) in the GNS-representations of \( \text{macroscopically pure} \) and \( \text{macroscopically stationary} \) states of the system.

### 6.5.5. The KMS-states of \((\mathfrak{A}; \tau^Q)\) at positive temperature \( T > 0 \):

The algebra \( \mathfrak{A} \) is separable, hence the representation space \( \mathcal{H}_\omega \) of any cyclic representation is separable and the \( \text{KMS-states} \ \omega \) of this system are supported by the \text{extremal KMS states}. This means, roughly speaking, that any KMS-state can be constructed as an integral of the extremal KMS states at the same temperature \( T \). Hence, the evaluation of all extremal KMS states is sufficient to characterization of all KMS states of the system. Let us consider now the extremal KMS states.
Any extremal $\tau^Q$-KMS state at $T > 0$ (hence at $\beta := T^{-1} \neq \infty$) is determined uniquely by its restriction $\omega^0$ to $\mathfrak{A}_0$, cf. Theorem 6.4.10 (remember that all states on the UHF-algebra $\mathfrak{A}$ are locally normal). Let $F_\omega \in g^*$ be the classical phase point corresponding to a given extremal $\tau^Q$-KMS state on $\mathfrak{A}$. Then the strong version (6.4.1) of the ‘consistency condition’ is valid, i.e.

$$\omega^0(X\xi) = F_\omega(\xi) \text{ for all } \xi \in g.$$  \hspace{1cm} (6.5.19)

Here $\omega^0$ is the (unique, if it exists) KMS-state on $\mathfrak{A}_0$ at the same temperature $T$ as the state $\omega \in \mathcal{S}(\mathfrak{A})$, corresponding to the evolution given by the generator $-X(\beta^Q_{F_\omega})$. There is one-one correspondence between the extremal $\tau^Q$-KMS states of the infinite system and the states $\omega^0$ satisfying the above listed conditions for some stationary point $F_\omega$ of the classical equations lying in the physical domain, $F_\omega \in \text{supp } E_g$.

Let a stationary point $F_\omega \in \text{supp } E_g$ be given. Then any $\sigma(\exp(-t\beta^Q_{F_\omega}))$-KMS state $\omega^0$ on $\mathfrak{A}_0$ coincides with the Gibbs state $\omega^0_T$ at some temperature $T$. The state $\omega^0_T$ is given by:

$$\omega^0_T(y) := \left(\text{Tr} \exp\left(\frac{a(F_\omega)}{T} n(F_\omega) \cdot \sigma\right)\right)^{-1} \text{Tr} \left(\exp\left(\frac{a(F_\omega)}{T} n(F_\omega) \cdot \sigma\right) y\right), \hspace{1cm} (6.5.20)$$

for all $y \in \mathfrak{A}_0$. It is sufficient to calculate (6.5.20) for $y = \sigma_j$, $j = 1, 2, 3$. We obtain

$$\omega^0_T(\sigma_j) = n_j(F_\omega) \tanh(T^{-1}a(F_\omega)), \hspace{1cm} j = 1, 2, 3,$$  \hspace{1cm} (6.5.21)

and the consistency condition (6.5.19) means:

$$n_j(F_\omega) \tanh(T^{-1}a(F_\omega)) = 2F_\omega(\xi_j), \hspace{1cm} j = 1, 2, 3,$$  \hspace{1cm} (6.5.22)

which is equivalent to the following conditions:

$$\frac{\lambda F_\omega(\xi_j)}{a(F_\omega)} \tanh(T^{-1}a(F_\omega)) = 2F_\omega(\xi_j), \hspace{1cm} j = 1, 2; \hspace{1cm} (6.5.23a)$$

$$\frac{\varepsilon}{a(F_\omega)} \tanh(T^{-1}a(F_\omega)) = 2F_\omega(\xi_3). \hspace{1cm} (6.5.23b)$$

These conditions are satisfied by $F_\omega = F$, where

(i) either (in the cases of arbitrary positive $\varepsilon$ and $\lambda$)

$$F_1 = F_2 = 0, \text{ and } F(\xi_3) := F_3 = \frac{1}{2} \tanh\left(\frac{\varepsilon}{T}\right), \hspace{1cm} T > 0,$$  \hspace{1cm} (6.5.24)

(ii) or (in the cases with $0 < 2\varepsilon < \lambda$)

$$F(\xi_3) = \frac{\varepsilon}{\lambda}, \hspace{1cm} 2a(F) = \lambda \tanh(T^{-1}a(F)), \hspace{1cm} 0 < T < T_\varepsilon := \varepsilon \left(\tanh^{-1}\left(\frac{2\varepsilon}{\lambda}\right)\right)^{-1}. \hspace{1cm} (6.5.25)$$
Note that the condition (6.5.25) can be fulfilled with $F_+ \neq 0$ only, hence the sets of values $F \in \mathfrak{g}^*$ determined by the two conditions (6.5.24) and (6.5.25) are mutually disjoint. These relations allow us to give the list of all $F_\omega$ corresponding to extremal $\tau^Q$-KMS states at a given temperature $T > 0$:

(i) $T \geq T_c$; in this case $F_\omega(\xi_1) = F_\omega(\xi_2) = 0$, $F_\omega(\xi_3) = \frac{1}{2} \tanh \left( \frac{\varepsilon}{T} \right)$.

(ii) $0 < T < T_c$; here one has a state with $F_\omega$ described in (i) above, and, if $0 < 2\varepsilon < \lambda$, one has, moreover, a one-parameter family of possible $F_\omega \in su(2)^*$ such that:

$F(\xi_3) = \frac{\varepsilon}{\lambda}$, $2a(F_\omega) = \lambda \tanh(T^{-1}a(F_\omega))$.

There is one-one correspondence between the elements $F_\omega$ corresponding to a given value of $T > 0$ in this list and the extremal $(\tau^Q, \beta := T^{-1})$-KMS states of the infinite quantal system.

We see that, in the considered model, a KMS-state exists at any positive $T$, and for $T \geq T_c$ this state is unique. For $0 < T < T_c$, except of the ‘trivial possibility’ (6.5.24), there is a circle of points $F_\omega \in \mathfrak{g}^*$ numbering the elements of pairwise mutually disjoint extremal KMS states at the same temperature. If we call the subgroup $\exp(t\xi_3)$ the ‘gauge group’, then the gauge-invariant KMS-states exist at all $T > 0$ (the trivial possibilities (6.5.24) are gauge invariant); the extremal KMS states for temperatures $0 < T < T_c$ are not invariant with respect to the gauge group and they are transformed by the group actions into one another: here appears the spontaneous symmetry breaking phenomenon. For $0 < T < T_c$, there is another gauge invariant state $\omega_T^s \in K_\beta \subset \mathcal{S}(\mathfrak{A})$, $\beta := T^{-1}$, given by the integral of the states $\omega_T^F \in \mathcal{E}K_\beta$ corresponding to the values $F$ from (6.5.25):

$\omega_T^s(y) = \frac{1}{2\pi} \int_0^{2\pi} \omega_T^F(\sigma(\exp(t\xi_3))(y)) \, dt$, $0 < T < T_c$.  

(6.5.26)

Let us denote by $\omega_T^0$ the (extremal) KMS-state at $\beta = T^{-1}$ corresponding to the values (6.5.24) of $F_\omega = F$. The states $\omega_T^0$ ($T > 0$) are interpreted as describing the ‘normal conducting phase’, and the states $\omega_T^s$ ($T < T_c$) represent the ‘superconducting phase’. The mixtures $\omega_T := \lambda \omega_T^s + (1 - \lambda) \omega_T^0$ are also $(\tau^Q, \beta = T^{-1})$-KMS states at $0 < T < T_c$, $0 \leq \lambda \leq 1$. The equilibrium states of the considered system can be defined as the thermodynamic limits of the (unique) Gibbs states of local systems $(\mathfrak{A}^J; \tau^J)$, $|J| < \infty$, where $\tau^J_t \in \ast$-Aut $\mathcal{A}^J$ is generated by the local Hamiltonians $Q^J$ defined in (6.1.1). According to [168], these thermodynamic limits coincide with $\omega_T^s$ for $T \geq T_c$, whereas for $0 < T < T_c$ the limit $J \to \Pi$ leads to the state $\omega_T^s$.

6.5.6. The ground states of $(\mathfrak{A}; \tau^Q)$:

Let us consider now an extremal $\tau^Q$-ground state $\omega$ of our system, $\omega \in \mathcal{E}K_\infty$. Let $F_\omega$ be the corresponding classical stationary point in supp $E_\theta$. The restriction $\omega^0$ of $\omega$ to the
subalgebra $\mathfrak{A}_0$ is the unique ground state of the generator $X(\beta^Q_F)$, (6.5.15), corresponding to the eigenvector $\chi(F_\omega) \in \mathbb{C}^2$ with the minimal eigenvalue:

$$n(F) \cdot \sigma \chi(F) = \chi(F), \ F \in su(2)^*.$$  \hfill (6.5.27)

Due to the uniqueness of the ground state $\omega^0 \in \mathcal{S}(\mathfrak{A}_0)$ corresponding to a given $F_\omega \in su(2)^*$, any extremal $\tau^Q$-ground state is an $\pi(\Pi)$-invariant product state. Conversely, the $\pi(\Pi)$-invariant product state constructed from a vector $\chi(F)$ defined in (6.5.27) will be a pure ground state of $(\mathfrak{A}; \tau^Q)$ iff the ‘consistency condition’ [(\(\chi_1, \chi_2\) is here the scalar product in \(\mathbb{C}^2\)]

$$(\chi(F), X(\xi)\chi(F)) = F(\xi), \ \xi \in su(2),$$  \hfill (6.5.28)

will be satisfied. This is a consequence of the considerations in Section 6.4. Let us solve (6.5.28) for $F$. For $\xi := \xi_j$ ($j = 1, 2, 3$) one has

$$n_j(F) = 2F(\xi_j), \ j = 1, 2, 3,$$  \hfill (6.5.30)

where $n_j(F)$ is defined in (6.5.17). The obtained condition

leads to the following possibilities for $F = F_\omega$, $\omega \in \mathcal{E}_{K\infty}$:

(i) if $\varepsilon$ and $\lambda$ are arbitrary positive, then one can have:

$$F_1 = F_2 = 0, \ F_3 = \frac{1}{2};$$  \hfill (6.5.31)

(ii) for $0 < 2\varepsilon < \lambda$, one has, moreover, the possibilities:

$$F_1^2 + F_2^2 = \frac{1}{4} - \left(\frac{\varepsilon}{\lambda}\right)^2, \ F_3 = \frac{\varepsilon}{\lambda}.$$  \hfill (6.5.32)

Hence, in the case $0 < 2\varepsilon < \lambda$, the set of ground states has similar classical picture in $su(2)^*$ as the set of $\tau^Q$-KMS states with temperatures lying under the ‘critical temperature’ $T_c$. Let $\omega_0^\varepsilon \in \mathcal{K}_{\infty} \subset \mathcal{S}(\mathfrak{A})$ corresponds to the value $F_\omega$ from (6.5.31), and let $\omega_0^\varepsilon$ be given by (6.5.26) with $T = 0$ and with $\omega_0^F \in \mathcal{E}_{K\infty}$ corresponding to any value of $F$ given in (6.5.32). According to [168], the thermodynamic limit of the (unique) local ground states on $\mathfrak{A}^J$ corresponding to the Hamiltonians $Q^J$ coincides with $\omega_0^\varepsilon$. 
Chapter 7

Some models of “quantum measurement”

7.1 Introductory notes

7.1.1. The interactions in the models of large quantal systems described in Chapter 6 were of specific long-range type. All the elementary subsystems (“particles” or “spins”) mutually interacted with each other ‘in the same way’ as if all the subsystems were not distinguishable from each other, i.e. the multi-particle interaction was invariant with respect to permutations of the particles independent of their positions in the lattice Π, as specified by (6.1.1). Such interactions led in infinite limit of the number \( N \) of the subsystems to the dynamics of “mean-field type”, i.e. to such a dynamics that each individual subsystem moved as if it was immersed in an external (in general time dependent) field produced by the whole collection of the infinite number of all the subsystems and independent of any changes of the state of any of these subsystems. The resulting dynamics was such that macroscopic (classical) parameters of the infinite system were varying in time according to the dynamics of some classical mechanical Hamiltonian system.

In this chapter we will describe several specific models of large quantal systems whose elementary subsystems interact by short range interactions. The macroscopic, or “classical”, variables of the infinite systems will change now just in the limit \( t \to \infty \), because the short range interaction results in finite velocity of spreading of local changes across the infinite system, hence in finite times only local variables corresponding to changes of finite subsystems are changed.

7.1.2. We shall briefly describe here a few quantum-mechanical model systems describing interactions of a ‘microscopic system’ with a ‘macroscopic system’ leading to a ‘macroscopic change’ in the second system. This means that such systems describe schemes modeling dynamics of processes like ‘quantum measurement’ as a process ascribing a classical probability distribution of ‘measurement results’ (given by macroscopically distinct states of the ‘macroscopic system’ which plays the role of the ‘measuring apparatus’) to the corresponding (according to the ‘measured observable’) quantum-mechanical linear decomposition of the wave function of the ‘microscopic system’. Construction of these models was inspired mainly by the classical
7.1. INTRODUCTORY NOTES

paper by Klaus Hepp [153], cf. also [253, 254]. According to the previous chapters, we are able to describe in QM in a mathematically clear way macroscopic systems (with coordinates undergoing classical behaviour) by models of infinite quantal systems only. Of course, the infinity of the number of degrees of freedom should be considered as a convenient approximation to large but finite systems. Also infinite time duration of the processes of changing macroscopic parameters corresponding to considered microscopic influences is connected with this infinity. In this connection, it is relevant to be interested in the speed of the corresponding macroscopic changes. In the ‘infinite models’ presented here the convergence to a macroscopic change is very slow.

A much larger speed of convergence is reached in the model of finite (arbitrary long) ‘Quantum Domino’ - spin chain (cf. 7.1.3 and Sec 7.3) interacting with fermion field in such a way that after all the spins in the chain changed their orientations into the opposite ones the chain emits a fermion. In this case the speed of convergence to final stationary state is ‘almost exponential’. The model is described in [39]. Its interpretation as “a model of quantum measurement” is, however, questionable: Due to its finite dimension a definition of “macroscopic difference” is ambiguous and it would need probably a longer discussion. Cf. notes on this problem in the original Hepp’s work [153], and also in our Section 7.7.

It should be stressed that we do not intend to present the described models of micro-macro interaction as a definitive solution of the ‘measurement problem in QM’, cf. Sec. 7.7. They could be considered rather as an illustration of possibilities of the standard quantum mechanical formalism to include, by using this specific way of description of macroscopic observables, some descriptions of possible responses of large systems (hence changes of their ‘macroscopic variables’) to some of their interactions with microsystems. It is shown how can various states of a microsystem interacting with a macroscopic lead in QM to various ‘corresponding changes’ of values of their macroscopic (resp. ‘classical’) observables.

7.1.3. We present here four models, the second of which is based on the first one, the ”Quantum Domino” (QD), published originally in [36]. The idea of the third model is similar to that of QD, but it is based on the known X-Y model of the spin chain [201]. QD is a model of an infinite quantum system - an infinite (or semiinfinite) spin chain with a short range interaction - in which any local (microscopic) change of a specific stationary state leads to subsequent evolution (with time $t \to \infty$) to a new, macroscopically different stationary state. The initial local changes of these stationary states of this model are realized “by hand”, i.e. a locally perturbed stationary state is chosen as an initial condition for the forthcoming time-evolved states of that system. This local perturbation can be realized by a change of quantum state of a single spin (say the first one in the semiinfinite chain), and this spin can be considered, e.g. as an additional microsystem (the ‘measured system’) interacting with the infinite rest of the chain.\footnote{In the case of some different choices of (locally perturbed stationary) initial states in this model, the subsequent time evolutions of the chain could be different: e.g., an initial segment could move quasiperiodically and the infinite rest of the chain will converge to a macroscopically different state.}

The second model consists in the composition of two systems: of the previous (QD) one and of a point particle scattered on it; the QD-spin chain occurs initially in its specific stationary
state. The scalar particle (moving in the configuration space $\mathbb{R}^3$) perturbs locally the infinite system (by scattering on its ‘first two’ spins) and the chain develops then (after $t \to \infty$) with some probability to a macroscopically different state. This process can be interpreted as modeling detection of the particle by a macroscopic detector. The model is interesting by that that it does not correspond to an “ideal measurement” the results of which are described usually by a projector valued measure (PVM) realizing, e.g., the spectral decomposition of some selfadjoint operator - the ‘measured observable’. In our case, however, we obtain a positive operator valued measure (POVM) describing the probabilities of responses to incoming states of the particle; this expresses the technical characteristics of the detector with less than 100% efficiency. This model is presented here in detail, since it is presented here for the first time - it is a more complex and more complete version of an older model. The original version of this model was published in [38].

The third presented model is based on an ‘X-Y modification’ of the Heisenberg spin-chain models, cf. e.g. [267]. This “model of quantum measurement” consists of the 1/2-spin chain with a nearest neighbour interaction, which is interrupted in one link, and in the point of the interruption an additional 1/2-spin modeling a simplest possible “measured microsystem” is included (together with its interaction with the rest of chain).

The fourth model consists of a finite portion of QD of the length $N \gg 1$ coupled to Fermi field and working so that in the initial state “all the $N$ spins are pointing down”, but after reversing the first spin the chain moves until all the spins are “pointing up” and, after reversing the last $N$-th spin, the chain emits a Fermi particle. With the time $t \to \infty$ the particle moves freely to infinity and the chain remains in a new stationary state with “all spins pointing up”. The finite length of the chain needs a different interpretation as a “measuring device” in comparison with the preceding three infinite models.

7.2 On ‘philosophy’ of ”models”

The term ”model” is used repeatedly in this Chapter, as well as in science in general. This word is generally used in various connections and meanings. It is usually considered as denoting human constructs (material or mental) approximating in some way an aspect of a considered ‘part of reality’. But, can we determine where there is a borderline between ‘only approximation’ and ‘full picture of truth’? What is the ‘reality’? What is the meaning of ‘the truth’ (as it was asked also by Pontius Pilate very appropriately in Bible - New Testament: John 18:38)?

Let us consider (not only here) any human symbolic formulation of any knowledge as a “model”. Hence, also our laws of nature including the whole physics are models - they are provisional and waiting for further completions and/or reformulations.

It is motivating and orientating for researchers to believe in the existence of some ‘final truth’. It is an important psychological aspect of scientific progress. The faith in our ‘reliably verified knowledge’ is perhaps necessary also for the success of our practical life. But if a theory is completed (i.e. if it is in agreement with all available ‘trustworthy’ experimental results), it can be (and eventually should be) challenged in science.

Any theory, as well as any concept appearing in our consciousness or/and used in our
7.3. QUANTUM DOMINO

communication is a human construction. Hence it is dependent on human interests and activities, and these activities are perpetually evolving—sometimes even substantially changing. Hence, also our attention and interests are changing. This implies that the motives for our intellectual activity are perpetually developing. The resulting our ‘pictures of the world’, either global, or various special, are correspondingly changing along with these other changes. And, people also look then on ‘the same things’ by different ways and from different points of view than before.

The ‘models’ presented in this chapter are just very simple abstractions imitating certain features of mutual interactions of general classes of physical systems: microsystems described adequately by QM, and macroscopic systems (usually described by CM) consisting of a large number of microsystems. We tried to be mathematically rigorous in proceeding from basic axioms of QM to definitions of introduced concepts and constructions of the mathematical models, as well as to description and obtaining the consequences of the used dynamics. This emphasis on mathematical rigor was motivated by our desire to show clearly that the obtained results are exact consequences of the currently generally accepted formal theory of QM.

7.3 Quantum Domino

7.3.1. We shall describe here briefly (for more details we refer to [35, 36]) the model of infinite spin chain which we call, due to the character of its time evolution, Quantum Domino (QD). The 1/2 spins are ordered by the values of the index \( i \in \mathbb{Z} \) and the Hamiltonian produces a local nearest three body interaction. This interaction can be described easily as follows: If the hamiltonian acts on the state with the \( i \)-th spin ”pointing up” and the \((i+2)\)-nd spin ”pointing down”, then the \((i+1)\)-st spin changes its orientation to the opposite one. The dynamics of the two sided infinite spin-1/2 quantum chain has spin configurations “all spins pointing up”, and “all spins pointing down” as stationary states, which are unstable: If we reverse the direction of one of the spins in these states, the new state will develop in the limit \( t \to \infty \) into another stationary (and ‘macroscopically’ stable) state, in which all the spins lying on one side of the reversed spin are also reversed, and all the spins lying on the other side of that spin stay unchanged. Since this evolution leads to the change of the value of a macroscopic observable of the chain, it can be used as a model for ‘quantum measurement’ of microscopic observables of a single spin of the chain. We shall show in this section how such model works.

7.3.2. Let the \( C^* \)-algebra of observables \( \mathfrak{A} \) be the \( C^* \)-tensor product of countably infinite set of copies of the algebra of complex \( 2 \times 2 \) matrices generated by the spin creation and annihilation operators \( a_j^*, a_j \), \( j \in \mathbb{Z} \) satisfying the following (anti)commutation relations

\[
\begin{align*}
    a_i a_j - a_j a_i &=: [a_i, a_j] = [a_i^*, a_j] = 0, \quad i \neq j \\
    a_i a_i &= 0, \quad a_i^* a_i + a_i a_i^* = 1,
\end{align*}
\]

for all \( i, j \in \mathbb{Z} \). The algebra \( \mathfrak{A} \) is simple, hence each its nonzero representation is faithful. We shall describe the dynamics in \( \mathfrak{A} \) in the “vacuum” representation, i.e. in the GNS representation corresponding to the “vacuum state” \( \omega_0 \in \mathfrak{A}^*_+ - 1 \equiv S(\mathfrak{A}) \) that is given by the relation
\[ \omega_0(a_j^*a_j) = 0, \text{ for all } j \in \mathbb{Z}. \] (7.3.2)

This state is pure, hence the GNS representation is irreducible. We shall call the spins in this state to be “pointing down”, to be specific in verbal expression. Let the cyclic vector (“vacuum” in the lattice gas terminology) of this representation be denoted by \( \Omega_0 \), i.e. for all elements \( x \in \mathfrak{A} \) it is

\[ \omega_0(x) = \langle \Omega_0 | x \Omega_0 \rangle, \text{ for all } x \in \mathfrak{A}. \] (7.3.3)

Here and in the following we shall denote the elements of \( \mathfrak{A} \) and their operator representatives in the considered irreducible Hilbert space representation by the same symbols. Let us denote this Hilbert space by \( \mathcal{H}_{vac} \).

Let us define a “finite-subchain Hamiltonian” \( H_{(j,k)} \):

\[ H_{(j,k)} := \sum_{n=j+1}^{k-2} a_n^*a_n(a_{n+1}^* + a_{n+1})a_{n+2}a_{n+2}^*. \] (7.3.4)

Local time evolution automorphisms of \( \mathfrak{A} \) are given by

\[ \tau^n_t(x) := \exp(itH_{(-n,n)})x \exp(-itH_{(-n,n)}), \] (7.3.5)

and the norm limits

\[ \tau_t(x) := \text{norm- lim } \tau^n_t(x) \] (7.3.6)

determine the time evolution in \( \mathfrak{A} \) (in the “Heisenberg picture”).

In our vacuum representation, this evolution is determined by a selfadjoint Hamiltonian \( H \),

\[ \tau_t(x) = e^{itH}x e^{-itH}. \] (7.3.7)

Here, the (unbounded) operator \( H \) can be written in the evident form (its obvious definition and a proof of selfadjointness is given in [36, Prop.II.1])

\[ H := \sum_{n \in \mathbb{Z}} a_n^*a_n(a_{n+1}^* + a_{n+1})a_{n+2}a_{n+2}^*. \] (7.3.8)

This evolution is time-reflection invariant, but it is not invariant with respect to the space reflection \( n \mapsto -n \). Let us introduce the operators

\[ g_j := a_j^*a_{j+1}^*a_{j+1}. \]

These quantities are integrals of motion. One can also prove that the Hilbert space \( \mathcal{H}_{vac} \) can be decomposed into \( H \)-invariant orthogonal subspaces and on each of them the restriction of the Hamiltonian \( H \) is a bounded operator.

Let \( X \subset \mathbb{Z} \) be of finite cardinality, and let \( \Omega_X := \prod_{j \in X} a_j^* \Omega_0 \). The vectors \( \Omega_X \) with all mutually distinct finite \( X \subset \mathbb{Z} \), with \( \Omega_\emptyset := \Omega_0 \), form an orthonormal basis in \( \mathcal{H}_{vac} \). Each
finite $X \subset \mathbb{Z}$ is of the form $Y_1 \cup Y_2 \cup \cdots \cup Y_r$, where all $Y_k \subset \mathbb{Z}$ are nonempty finite, mutually disjoint and of the form $\{j_k+1, j_k+2, \ldots, j_k+m_k\}$, with $j_{k+1} > j_k + m_k$, $|Y_k| \equiv m_k$, i.e. the sets $Y_k \subset X$ ($k = 1, 2, \ldots, r$) form mutually separated “connected islands” consisting of “pointing up” spins. All the vectors $\Omega_X$ are eigenvectors of all the operators $g_j$. For the set $X$ of the just described structure we have

$$g_j \Omega_X = \begin{cases} \Omega_X & \text{for } j = j_k, \ k = 1, 2, \ldots, r \\ 0 & \text{otherwise.} \end{cases} \quad (7.3.9)$$

This implies that the time evolution of the vectors $\Omega_X$ conserves the number of islands, leaving the initial (“left”) points $j_k + 1$ of each $Y_k$ ($k = 1, 2, \ldots, r$) unchanged (“occupied”, or “pointing up”), and the places $j_k, \ k = 2, 3, \ldots, r$ as well as $j_1 - n$ ($n \in \mathbb{Z}_+$) remain all the time “unoccupied” (i.e. spins are there “pointing down”). Hence, the subspaces $\mathcal{H}_{\{j\}}$ spanned by all such vectors with a fixed set $\{j\} := \{j_1, j_2, \ldots, j_r\}$ are left invariant with respect to to the action of the Hamiltonian $H$. Then the space $\mathcal{H}_{\text{vac}}$ decomposes as

$$\mathcal{H}_{\text{vac}} = \bigoplus_{\{j\}} \mathcal{H}_{\{j\}}, \quad (7.3.10)$$

where the orthogonal sum is taken over all mutually different $\{j\}$; note that the stationary subspace $\mathcal{H}_{\{0\}} := \{\lambda \Omega_0 : \lambda \in \mathbb{C}\}$ is one dimensional.

The structure of the Hamiltonian $H$ shows, moreover, that each $\mathcal{H}_{\{j\}}$ can be written as (i.e. it is isomorphic to) the tensor product of a vector (resp. of a one-dimensional subspace) and a finite number of Hilbert spaces corresponding to restricted subchains of spins:

$$\mathcal{H}_{\{j\}} = \Omega_0^{(-\infty, j_1)} \otimes \mathcal{H}_{(j_1, j_2)} \otimes \mathcal{H}_{(j_2, j_3)} \otimes \cdots \otimes \mathcal{H}_{(j_r, +\infty)}, \quad (7.3.11)$$

where $\Omega_0^{(-\infty, j_1)}$ is one-dimensional space containing the vector with all spins numbered by $j \leq j_1$ “pointing down”, and the spaces $\mathcal{H}_{(j_k, j_{k+1})}$ are spanned by $j_{k+1} - j_k - 1$ vectors corresponding to the “islands” $Y_k$ of all permitted lengths $1 \leq |Y_k| < j_{k+1} - j_k$. Here we understand that $j_{r+1} \equiv +\infty$. We see from the form of the Hamiltonian that the time evolution of vectors in the subspaces $\mathcal{H}_{\{j\}}$ is described by (“mutually independent”) evolutions in each $\mathcal{H}_{(j_k, j_{k+1})}$ determined by the Hamiltonians $H_{(j_k, j_{k+1})}$, cf. (7.3.4); for more details see [36, 35].

7.3.3. The result of these considerations is that the evolution of general vectors of our representation (hence also the evolution of any states from $\mathcal{S}(\mathcal{A})$) can be described by two simpler kinds of evolution, namely, the evolutions in finite chains described by Hilbert spaces $\mathcal{H}_{(j_k, j_{k+1})}$, as well as in the Hilbert spaces $\mathcal{H}_{(j_r, +\infty)}$ spanned by vectors of arbitrary one-sidedly unrestricted lengths. Because the interaction in our infinite chain is translation invariant, we can describe these two possibilities as\footnote{We shall use here the Dirac bra - ket notation for convenience.}

1. the evolution in the finite-dimensional Hilbert space $\mathcal{H}_{(0, N+1)}$ spanned by the vectors

$$|m\rangle := a_1^* a_2^* \cdots a_m^* \Omega_0 \ (m = 1, 2, \ldots, N) \quad (7.3.12a)$$
by the unitary evolution group $U_N(t) := e^{-itH_N}$ with the Hamiltonian $H_N := H_{(0,N+1)}$ from (7.3.4), and

(2) the evolution in the infinite-dimensional Hilbert space $\mathcal{H}_{(0,\infty)}$ spanned by the vectors

$$|m\rangle := a_1^* a_2^* \ldots a_m^* \Omega_0 \quad (m \in \mathbb{Z}, m \geq 1)$$

(7.3.12b)

by the unitary evolution operators $U_{\infty}(t) := e^{-itH}$ with the Hamiltonian $H := H_{(0,\infty)}$.

Let us express these two instances of dynamics by the matrix elements $\langle n | U(t) | m \rangle$. The result can be obtained by explicitly solving the eigenvalue problem for $H_N$. The action of $H_N$ is:

$$H_N|1\rangle = |2\rangle,$$  \hspace{1cm} (7.3.13a)

$$H_N|m\rangle = |m - 1\rangle + |m + 1\rangle, \quad m = 2, 3, \ldots, N - 1,$$  \hspace{1cm} (7.3.13b)

$$H_N|N\rangle = |N - 1\rangle,$$  \hspace{1cm} (7.3.13c)

$$H_N|k\rangle = 0 \text{ for } k > N.$$  \hspace{1cm} (7.3.13d)

For the eigenvectors $\psi_E : H_N \psi_E = E \psi_E$ written in the basis of vectors $|m\rangle$:

$$\psi_E = \sum_{m=1}^{N} c_m(E) |m\rangle$$  \hspace{1cm} (7.3.14)

we obtain the eigenvalue problem in the form:

$$Ec_1(E) = c_2(E),$$  \hspace{1cm} (7.3.15a)

$$Ec_m(E) = c_{m-1}(E) + c_{m+1}(E), \quad m = 2, 3, \ldots, N - 1,$$  \hspace{1cm} (7.3.15b)

$$Ec_N(E) = c_{N-1}(E).$$  \hspace{1cm} (7.3.15c)

The equations (7.3.15) lead to

$$c_m(E) = \mathcal{U}_{m-1}(E/2)c_1(E),$$  \hspace{1cm} (7.3.16)

where

$$\mathcal{U}_{m-1}(z) := \frac{\sin(m \arccos z)}{\sin(\arccos z)}$$  \hspace{1cm} (7.3.17)

are the Tshebyshev polynomials of the second kind [129, 8.940]. This is seen from the recurrent relations for $\mathcal{U}_n$ following from (7.3.15), cf. [36, III.(27)]:

$$\mathcal{U}_{n+1}(z) = 2z \mathcal{U}_n(z) - \mathcal{U}_{n-1}(z), \quad \mathcal{U}_0(z) = 1, \quad \mathcal{U}_1(z) = 2z.$$  \hspace{1cm} (7.3.18)

The equation (7.3.15c) has now the form

$$\mathcal{U}_N(E/2) = 0,$$  \hspace{1cm} (7.3.18)
which is the secular equation corresponding to our eigenvalue problem. Its solutions are

$$E_j = 2 \cos\left(\frac{j\pi}{N+1}\right), \ j = 1, 2, \ldots, N,$$  \hspace{1cm} (7.3.19)

hence we have the expressions

$$c_m(E_j) = \left[\frac{2}{N+1}\right]^{1/2} \sin\left[\frac{jm\pi}{N+1}\right].$$  \hspace{1cm} (7.3.20)

We shall need also the following definition:

$$J_n^{(N)}(z) := \frac{i^n}{N+1} \sum_{j=1}^{N} \exp\left[-iz \cos\left(\frac{j\pi}{N+1}\right)\right] \cos\left(n \frac{j\pi}{N+1}\right).$$  \hspace{1cm} (7.3.21)

This is an integral sum of Sommerfeld integral representation of the Bessel function $J_n(z)$, see also [129, 8.41]:

$$J_n(z) = \frac{i^n}{\pi} \int_0^\pi e^{-iz \cos\alpha} \cos(n\alpha) d\alpha.$$  \hspace{1cm} (7.3.22)

We can now write the desired expression for the Green function of a finite chain:

$$\langle n | U_N(t) | m \rangle = (-i)^{n-m} J_{n-m}^{(N)}(2t) - (-i)^{n+m} J_{n+m}^{(N)}(2t),$$  \hspace{1cm} (7.3.23)

what can be obtained by a standard way using the completeness the orthonormal system of vectors (7.3.14) in $\mathcal{H}_{0, N+1}$.

This, for an infinite chain with $N \to \infty$, gives:

$$\langle n | U_\infty(t) | m \rangle = (-i)^{n-m} J_{n-m}(2t) - (-i)^{n+m} J_{n+m}(2t).$$  \hspace{1cm} (7.3.24)

7.3.4. Let us now consider the local perturbation $\omega_1(x) := \omega_0(a_ja_j^\dagger)$ $(x \in \mathfrak{A})$ of the time-invariant vacuum state $\omega_0$. The state $\omega_1$ describes the infinite spin-chain in the state where all the spins except of the one sitting in the site $j = 1$ are pointing down. Its time evolution $\omega_1(\tau_t(x)) \equiv \omega_1^t(x)$ can be expressed in terms of the results given above. Let us, for example, calculate the expectation of “flipping up” of the spin placed in the $j$-th place at the time $t$. We have

$$\omega_1^t(a_j^*a_j) = \sum_{m=1}^{\infty} \langle 1 | e^{itH} a_j^*a_j | m \rangle \langle m | e^{-itH} | 1 \rangle = \sum_{m=j}^{\infty} \langle 1 | e^{itH} | m \rangle \langle m | e^{-itH} | 1 \rangle = 1 - \sum_{m=1}^{j-1} | \langle m | e^{-itH} | 1 \rangle |^2,$$  \hspace{1cm} (7.3.25)

since

$$a_j^*a_j | m \rangle = \begin{cases} 0 & (m < j), \\ | m \rangle & (m \geq j), \end{cases}$$
and the set of vectors \( \{|m\rangle : m \in \mathbb{Z}\} \) forms an orthonormal basis in the relevant Hilbert space. From (7.3.24) and from the recurrent formula for Bessel functions

\[
J_{p+1}(z) + J_{p-1}(z) = \frac{2p}{z} J_p(z),
\]

we obtain

\[
\omega^t_1(a^*_j a_j) = 1 - \sum_{m=1}^{j-1} \left[ \frac{m}{t} J_m(2t) \right]^2.
\]

Because of the asymptotic behaviour of the Bessel function for large real arguments \( |\xi| \to \infty \), given by \( J_p(\xi) = O(|\xi|^{-\frac{1}{2}}) \), we obtain asymptotic behaviour of our expectation:

\[
\omega^t_1(a^*_j a_j) \approx 1 - \text{const.} \frac{1}{|t|^3} \quad (\forall j \in \mathbb{N}) \text{ for } t \to \infty.
\]

Hence the local perturbation of the state “all spins are pointing down” converges according to (7.3.27) to the state “all spins sitting in sites with \( j > 0 \) are pointing up”. For more details see also [34, 35, 36].

### 7.3.5.

This can be used for construction of models imitating the ‘quantum measurement process’. For instance, let the infinite chain without the spin sitting in the site \( j = 0 \) model an “apparatus” and the spin at \( j = 0 \) serve as a “measured microsystem”. If the apparatus is initially in the state \( \omega_\downarrow \) with all its spins pointing down, and the measured spin in a superposition \( \varphi := c_\downarrow |\downarrow\rangle + c_\uparrow |\uparrow\rangle \), then the compound system “measured microsystem + apparatus” is in the time \( t = 0 \) in the state described by the state-vector \( c_\downarrow \Omega_0 + c_\uparrow a^*_0 \Omega_0 \), which is a coherent superposition of vectors in the ‘vacuum representation’ of the algebra of observables of the compound system. Then the final state of the chain (at \( t = \infty \)) will be (as a state on the algebra \( \mathfrak{A} \) of the compound system “measured system + apparatus”)\(^3\) in an incoherent genuine mixture \( \omega_f \) according to the above described dynamics: \( \omega_f = |c_\downarrow|^2 \omega_0 + |c_\uparrow|^2 \omega_\uparrow \), where the state \( \omega_\uparrow \) means that all spins of the compound system lying in sites \( j \geq 0 \) are pointing up, whereas the spins lying in sites \( j < 0 \) remain pointing down. The states \( \omega_0 \) and \( \omega_\uparrow \) on \( \mathfrak{A} \) are mutually disjoint; this is interpreted here as “macroscopic difference” of these states. Also, the states \( \omega_0 \) and \( \omega_\uparrow \) define two representations of the algebra of quasi-local observables (see also [53, 54, 274, 275] for further details) which are not unitary equivalent, and can be distinguished by a measurement of a macroscopic observable.

As the macroscopic observable distinguishing these states could be chosen, e.g., the weak limit \( \gamma \in \mathfrak{A}^{**} \) for \( n \to \infty \) of the sequence

\[
\gamma_n := \frac{1}{2n+1} \sum_{j=-n}^{n} a^*_j a_j,
\]

\(^3\)We consider here, for the sake of simplicity, the measured system after the measurement as a part of the apparatus, what makes no difference for observing results of measurements via various macrostates - the macroobservables of the compound system are identical with those of the measuring apparatus alone. See however the subsection 7.3.7 below.
and for the states \( \omega_0, \omega_\gamma \) (now considered as being extended to normal states on the von Neumann algebra \( \mathfrak{A}^{**} \)) we obtain: \( \omega_0(\gamma) = 0, \ \omega_\gamma(\gamma) = \frac{1}{2} \). This is an example in the spirit of the models proposed in the classical paper by Hepp [153] for modeling the "quantum measurement process".

7.3.6. Observable quantities in QM, or "observables", are described usually by selfadjoint operators \( A \) acting on the Hilbert space where the "observed" states of a considered physical system appear. In another setting, we can speak instead of a selfadjoint operator \( A \) on the projection-valued measure (\( \equiv \) projector-valued measure) (PM) \( \Lambda \mapsto E_A(\Lambda) \) for \( \Lambda \subseteq \Gamma \equiv A \equiv \) the set (with a given \( \sigma \)-algebra structure) of possible values of the observable (specifying the operator uniquely); here \( E_A(\Lambda) \) are mutually commuting orthogonal projectors satisfying \( \sigma \)-additivity with respect to \( \{ \Lambda \} \) set unions of various disjoint arguments \( \Lambda \subseteq \Gamma \), with \( E_A(\Gamma) = I_H \).

More general concept of "observable" in QM is again \( \sigma \)-additive positive operator valued measure (POVM) \( \Lambda \mapsto A(\Lambda), \) with \( A \in \mathcal{L}(\mathcal{H}), 0 \leq A(\Lambda) \leq A(\Gamma) = I_H, \Lambda_i \cap \Lambda_j = \emptyset \) \( (\forall i, j) \Rightarrow A(\cup_k \Lambda_k) = \sum_k A(\Lambda_k) \), which also specifies a selfadjoint operator \( A \), but is not specified by it uniquely. The different \( A(\Lambda) \subseteq \Gamma \), need not to be now mutually commutative. According to a general 'philosophy' of QM, to each observable corresponds a measuring apparatus (better: a class of equivalent apparatuses) characterized abstractly by the observable by which it can be measured. Conversely, if we perform a measurement on some quantum-mechanical system, some observable is measured. The results of the measurement of \( A \) on the state \( \varrho \) is found in the set \( \Lambda \subseteq \Gamma \) with the probability \( pr_A(\varrho, \Lambda) = Tr(\varrho A(\Lambda)) \).

If \( \Lambda \mapsto pr(\varrho, \Lambda) \) \( (\Lambda \subseteq \Gamma) \) is a probability measure for any \( \varrho \) and this mapping depends on \( \varrho \) affinely: \( pr(\lambda \varrho_1 + (1-\lambda) \varrho_2, \Lambda) \equiv \lambda pr(\varrho_1, \Lambda) + (1-\lambda) pr(\varrho_2, \Lambda) \), then there is a unique observable \( A \) of the measured system such that \( pr(\varrho, \Lambda) \equiv Tr(\varrho A(\Lambda)) \). If the distribution of the results of a measurement is expressed in this way by some POVM \( A \neq E_A \), the measurement is often called a nonideal measurement. For more complete formulations cf. [84, 149].

We are dealing in this work with infinite quantal systems described by \( C^* \)-algebras having many mutually inequivalent representations. Hence, we cannot restrict the concept of observables to operators acting e.g. on a Hilbert space \( \mathcal{H}_\omega \) of a specific cyclic representation. If we want stay in a framework of the above presented scheme, we can, and we presently shall, use the universal representation of \( C^* \)-algebra \( \mathfrak{A} \) in \( \mathcal{H}_\omega \), resp. of its weak closure, which is a \( W^* \)-algebra isomorphic to the double dual \( \mathfrak{A}^{**} \) of \( \mathfrak{A} \). For some comments on this reformulation see e.g. [84, Sec. 2.5].

7.3.7. We can now ask, which observable (in the sense of 7.3.6) was measured by the 'measuring apparatus' modeled by our QD, as it was sketched in 7.3.5. The 'microsystem' being measured consists in the spin sitting in the point \( j = 0 \) of the infinite spin-chain and the rest of the chain is the 'measuring apparatus'. Let us consider as the apparatus the half-infinite chain with spins sitting in the points numbered by \( j = 1, 2, \ldots, \infty \) only, because the spins sitting in the points with \( j < 0 \) do not take part in these measurements.\(^4\) An integral part of the characterization of the apparatus is, however, also its initial state 'with all spins pointing down', as well as its

\(^4\) In accordance with that, the notation in this subsection will be changed slightly with respect to the notation in the subsection 7.3.5.
dynamics including the interaction with the measured spin. The results of these measurements are read by looking at the final states of the apparatus.\footnote{We are speaking here about the states on the algebra generated by $a_j, a_j^*$ with $j > 0$ only.} There are just two possibilities in this process: The states $\omega_j$ with all spins pointing down, i.e. $\omega_j(a_j a_j^*) \equiv 1$, and the state $\omega_1$ with all spins pointing up, i.e. $\omega_1(a_j^* a_j) \equiv 1$, which is disjoint from the state $\omega_j$. If these states are (uniquely) extended to normal states on the double dual of the algebra of measuring apparatus, their values can be calculated on the ‘macroscopic observable’ $\gamma$ defined now as the weak limit of the sums

$$\gamma_n := \frac{1}{n} \sum_{j=1}^n a_j^* a_j.$$  \hfill (7.3.29)

Then it is $\omega_1(\gamma) = 0$, $\omega_\uparrow(\gamma) = 1$. The “spectral set” $\Gamma$ from 7.3.6 consists now of only two points, let us denote them (arbitrarily, but taking into account the actual measurement process) $\pm \frac{1}{\sqrt{2}}$, hence $\Gamma := \{\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\}$.

The initial (=measured) state of the ‘microsystem’ in the example of 7.3.5 was given by the normalized vector $|\phi\rangle := c_\downarrow |\downarrow\rangle + c_\uparrow |\uparrow\rangle$ corresponding to the density matrix $\varrho = |\phi\rangle\langle\varphi|$ being just the one-dimensional projector on the pure state $|\varphi\rangle$ of the measured system. The final state of the apparatus was in this case (according to 7.3.5) $\omega_f := |c_\downarrow|^2 \omega_\downarrow + |c_\uparrow|^2 \omega_\uparrow$, where $|c_\downarrow|^2$, $|c_\uparrow|^2$ are the desired probabilities $pr(\varrho, \pm \frac{1}{\sqrt{2}})$. From the linearity of the tensor products, as well as of time evolution, we can see that the extension of the previously introduced function $pr(\varrho, \pm \frac{1}{\sqrt{2}})$ to general density matrices $\varrho$ is an affine function of $\varrho$. Hence, e.g. for convex combination of two ‘pure’ density matrices,

$$\varrho := \lambda_1 |\phi_1\rangle\langle\phi_1| + \lambda_2 |\phi_2\rangle\langle\phi_2|$$

with $|\phi_j\rangle := c_{j\pm} |\downarrow\rangle + c_{j\uparrow} |\uparrow\rangle$, $j = 1, 2$, \hfill (7.3.30)

we obtain

$$pr(\varrho, -\frac{1}{2}) = \lambda_1 pr(|\phi_1\rangle\langle\phi_1|, -\frac{1}{2}) + \lambda_2 pr(|\phi_2\rangle\langle\phi_2|, -\frac{1}{2}) = \lambda_1 |c_{1\downarrow}|^2 + \lambda_2 |c_{2\downarrow}|^2,$$

$$pr(\varrho, \frac{1}{2}) = \lambda_1 pr(|\phi_1\rangle\langle\phi_1|, \frac{1}{2}) + \lambda_2 pr(|\phi_2\rangle\langle\phi_2|, \frac{1}{2}) = \lambda_1 |c_{1\uparrow}|^2 + \lambda_2 |c_{2\uparrow}|^2.$$

(7.3.31)

Let us define the operator $A := \frac{1}{2} |\uparrow\rangle\langle\uparrow| - \frac{1}{2} |\downarrow\rangle\langle\downarrow|$ on the Hilbert state space of the measured system. Its spectral projections are $P_\uparrow := |\uparrow\rangle\langle\uparrow|$ and $P_\downarrow := |\downarrow\rangle\langle\downarrow|$ and the corresponding mutually distinct eigenvalues are chosen to be $\pm \frac{1}{2}$. Then, for our density matrix there holds

$$pr(\varrho, -\frac{1}{2}) = Tr(P_\uparrow \varrho), \quad pr(\varrho, \frac{1}{2}) = Tr(P_\downarrow \varrho).$$

(7.3.32)

Hence, our measuring process corresponds to measurement of operators with PM given by the one-dimensional orthogonal projectors $P_{\uparrow, \downarrow}$. Our choice of the values of elements in the set $\Gamma$ corresponds to the observable describing a component of the $\frac{1}{2}\hbar$-spin, which is usually described in this way. We did not need here a generalized observable determined by a POVM, which will be, however, the case of the following example.
7.4 Particle detection - a “nonideal” measurement

7.4.1. This model describes a compound system of a spin chain \( A \) with a particle \( B \); it is a completed version of the model presented originally in [38]. The model of the spin chain is the half-infinite chain of the form described in the section 7.3, and the particle is a nonrelativistic scalar particle.

Let us use (essentially) the notation of section 7.3. Hence, the algebra \( \mathfrak{A} \) of the observables of the spin chain is now generated by the elements \( a_n^* a_n, \ n \geq 1 \). Let the Hamiltonian of the chain be the operator (cf. (7.3.8))

\[
H_A := \sum_{n \geq 1} a_n^* a_n (a_{n+1}^* + a_{n+1} a_{n+2}^* a_{n+2})
\]

acting in the Hilbert space \( \mathcal{H}_{vac} \) of the GNS-representation of \( \mathfrak{A} \) with bf the cyclic vector \( \Omega_0 \) corresponding to the state

\[
\omega_A^A(a_j^* a_j) = 0, \text{ for all } j \geq 1.
\]

The particle B is moving in the 3-dimensional Euclidean space and is described as in elementary QM by operators acting in the space \( \mathcal{H}_B := L^2(\mathbb{R}^3, d^3x) \), so that its states are described by vectors (resp. the corresponding unit rays) \( \psi \in \mathcal{H}_B \). The free particle’s Hamiltonian will be just the kinetic energy (in conveniently chosen units and in the “\( x \)-representation”)

\[
H_B := \hat{p}^2 = -\sum_{j=1}^3 \frac{\partial^2}{\partial x_j^2}.
\]

The interaction Hamiltonian will be \( V_\varphi \), with

\[
V_\varphi := (a_1^* + a_1) a_2 a_2^* \otimes |\varphi\rangle \langle \varphi| \in \mathcal{L}(\mathcal{H}_{vac} \otimes \mathcal{H}_B),
\]

where \( \varphi \equiv |\varphi\rangle \in \mathcal{H}_B \) is a conveniently chosen normalized vector, hence \( |\varphi\rangle \langle \varphi| \equiv P_\varphi \) is a one-dimensional projector in \( \mathcal{H}_B \).

The total Hamiltonian \( H \) of the compound system \( \{\text{spin chain & particle}\} \) will be

\[
H := H_A + H_B + \gamma V_\varphi, \ \gamma \in \mathbb{R}.
\]

Some restrictions on the interaction constant \( \gamma \) and on the unit vector \( \varphi \) will be specified later.

7.4.2. We want to prove, for conveniently chosen parameters \( \gamma \) and \( \varphi \) of interaction and for suitable initial states \( \psi \in \mathcal{H}_B \) of the particle as well as for given initial state of the spin chain with all spins “pointing down”, that the compound system will evolve for \( t \to \infty \) with positive probability into a convex combination of two mutually disjoint (hence ‘macroscopically different’) states, one of which corresponds to the unchanged initial state of the apparatus and in the other the apparatus has all its spins reversed to the “pointing up” direction. If we denote by \( \mathfrak{B} := \mathcal{L}(\mathcal{H}_B) \) the algebra of all bounded operators on \( \mathcal{H}_B \), which is the \( C^* \)-algebra of the observables of the particle, and by \( \mathfrak{C} := \mathfrak{A} \otimes \mathfrak{B} \) the \( C^* \)-algebra of the compound system, then
CHAPTER 7. SOME MODELS OF “QUANTUM MEASUREMENT”

\( S(\mathcal{C}) \) will be the state-space \( \mathcal{C}_+^{*1} \) (i.e. positive normalized elements of the topological dual of \( \mathcal{C} \)) of the compound system.

We will prove that the initial state \( \omega_0^{AkB} \equiv \omega_0^A \otimes \omega_0^B \in S(\mathcal{C}) \), where \( a \mapsto \omega_0^B(a) := \langle \psi | a | \psi \rangle \) for \( a \in \mathcal{B} \), will evolve to the state \( \varpi \in S(\mathcal{C}) \), \( \varpi = (w(\psi) \omega_0^A + (1 - w(\psi)) \omega_0^A) \otimes \omega_0^B \), and where \( \omega_0^B \in S(\mathcal{B}) \) is the state without particles, cf. 7.4.3, and \( 0 < w(\psi) < 1 \) for any of the considered initial state-vectors \( \psi \).

If we ask “which observable is measured by this process”, the relevant answer is – if we consider only the mathematical expression of the “observable” appearing in the question – in the expression of the probability \( w(\psi) \) as a diagonal matrix element of a positive operator \( W \equiv W_\gamma \) between the state vectors of the particle’s initial state \( \psi : w(\psi) = \langle \psi | W | \psi \rangle \).

The operator \( W, 0 < W < 1, W \neq W^2 \), replaces here the usual appearance of a projector from the PM of measured selfadjoint operator in the cases of “ideal measurements”, cf. also [149].

Our simple specific model represents more general instances of measurements: The “nonideal measurement” is described by a POVM (= positive operator valued measure). Hence, our model illustrates the concept of “generalized observables” introduced in [84, Sec.3.1], cf. also our 7.3.6 and 7.3.7, and its usefulness. The quantity \( w(\psi) = \langle \psi | W | \psi \rangle \) has to be interpreted as the measured probability of one of two possible results of a two-valued observable of the particles prepared at \( t = 0 \) in the state \( \psi \). A verbal expression of the intuitive physical meaning of “the particle’s observable \( W \)” might be here just something like “what can be registered by this specific measuring apparatus”, with two different pointer values: to be or not to be registered by this specific apparatus.

7.4.3 Notation. We shall use the following symbols:

1. The state without particles could be defined in a standard way, e.g. as the vacuum state in the Fock representation, where the algebra of observables of particles is constructed by creation-annihilation operators, cf. [38]. To avoid this (here unnecessary) complication, we shall define the no-particle state as the normal linear functional \( \omega_0^B \in S(\mathcal{B}) \) on \( \mathcal{B} = \mathcal{L}(\mathcal{H}_B) \), \( \omega_0^B : b \mapsto \omega_0^B(b) \) (remember that \( \dim \mathcal{H}_B = \infty \)) such that

\[
\omega_0^B(b) = 1, \text{ if } b = I_{\mathcal{H}_B}; \quad \omega_0^B(b) = 0, \text{ if } b = |\psi_1\rangle\langle\psi_2|, \quad \psi_j \in \mathcal{H}_B.
\]

This will give equivalent results of our considerations to those obtained from the considerations using the formalism of nonrelativistic quantum field theory.

2. Let us introduce also the symbol \( \mathcal{H}_A \) for the Hilbert (sub-)space of the chain generated by the vectors \( \{|m| \mid m = 1, 2, \ldots \} \) introduced in (7.3.12). We shall use also: \( U_t := \exp(-itH) \) with \( H \) from (7.4.5), and \( \tau_c := e^{itH}c e^{-itH} \) for \( c \in \mathcal{C} \). The vector \( \Omega_0 = |0\rangle \) is defined in (7.3.2) and (7.3.3). We shall also use \( \Omega_0^\chi := \Omega_0 \otimes \chi, \chi \in \mathcal{H}_B \).

3. Let \( \varphi \in \mathcal{H}_B, \|\varphi\|_2 = 1 \), be the vector appearing in the interaction Hamiltonian \( V_\varphi \) in (7.4.4), and let \( \psi \in \mathcal{H}_B \) be the (also normalized) initial state-vector of the particle.

We shall introduce the symbols \( F_0(t), g(t), \) and \( F(t) \) as:

\[
F_0(t) \equiv F_\varphi^0(\psi)(t) := \langle \varphi | e^{-itH_B} | \psi \rangle, \quad g(t) := F_\varphi^0(\varphi)(t) \equiv \langle \varphi | e^{-itH_B} | \varphi \rangle.
\] (7.4.6a)
7.4. PARTICLE DETECTION - A “NONIDEAL” MEASUREMENT

\[ F(t) \equiv F_\varphi(\psi)(t) := \langle \varphi \rangle \otimes (0|e^{-itH}|0) \otimes |\psi \rangle \equiv \langle \Omega_0^\varphi |e^{-itH}|\Omega_0^\psi \rangle, \]  

(7.4.6b)

where \( H := H_A + H_B + \gamma V_\varphi \) is the total Hamiltonian of the compound system (7.4.5).

The symbols \( f_m(t), f(t) \) will be also useful abbreviations (cf. (7.3.24)):

\[
\begin{align*}
    f_m(t) &:= \langle m|e^{-itH_A}|1 \rangle = (-i)^m \frac{m}{t} J_m(2t), \quad m = 1, 2, \ldots \\
    f(t) &:= g(t)f_1(t) = \langle \varphi \rangle \otimes (1|e^{-it(H_A+H_B)}|1) \otimes |\varphi \rangle.
\end{align*}
\]

(7.4.7)

(7.4.8)

4. To restrict a function \( t \mapsto h(t) \) defined on the whole real line \( t \in \mathbb{R} \) to the positive (resp. negative) values of its argument \( t \in \mathbb{R}^+ \) (resp. \( \mathbb{R}^- \)), we shall use the (Heaviside) \( \theta(t) \)-function equal to zero for \( t < 0 \) and equal to one for \( t \geq 0 \). We shall denote these restrictions as \( h_\pm(t) \):

\[
h_+(t) := \theta(t)h(t), \quad \text{resp.} \quad h_-(t) := \theta(-t)h(t), \quad t \in \mathbb{R}.
\]

(7.4.9)

Such restrictions \( f \mapsto f_+ \) will be useful here, e.g., for rewriting certain equations in the convolution form.

5. The convolution \( f \ast h(t) \) of two complex-valued integrable functions is defined by

\[
f \ast h(t) = \int_{-\infty}^{+\infty} d\tau f(t - \tau)h(\tau) = h \ast f(t).
\]

(7.4.10)

For more details on existence conditions of convolutions see e.g. [262, IX.4]. The operation \( \ast \) is not only commutative, but also associative. It can be trivially extended to functions \( t \mapsto h(t) \) defined for \( t \in \mathbb{R}^n \), as well as to some other classes of functions and of distributions, see e.g. [262, 324].

6. Let us define and denote, for purposes of the present section, to any integrable function \( h \in L^1(\mathbb{R}) \), its Fourier transformed function \( \mathcal{F}(h) \equiv \hat{h} \):

\[
\hat{h}(u) \equiv \mathcal{F}(h)(u) := \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} e^{-itu}h(t) \, dt, \quad u \in \mathbb{R}.
\]

(7.4.11a)

In the case of higher dimensional arguments of the \( \mathbb{C} \)-valued functions \( h \in L^1(\mathbb{R}^n) \) the analogous formula applies:

\[
\hat{h}(u) \equiv \mathcal{F}(h)(u) \equiv \mathcal{F}(h(t))(u) := (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{-it \cdot u} h(t) \, d^n t, \quad u \in \mathbb{R}^n.
\]

(7.4.11b)

The inverse \( \mathcal{F}^{-1} \) of \( \mathcal{F} \) defined on the image \( \hat{h} = \mathcal{F}(h) \) has the similarly looking form:

\[
h(t) = \mathcal{F}^{-1}(\hat{h})(t) = \mathcal{F}(\hat{h}(-u))(t) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{it \cdot u} \hat{h}(u) \, d^n u, \quad t \in \mathbb{R}^n.
\]

(7.4.11c)
Generalizations to various classes of functions and also to tempered distributions is very useful in process of solution of various equations. Many important properties of the Fourier transformation can be found, e.g. in [262, 324]. One of the most useful properties of $F$ is the possibility to extend it from $L^1(\mathbb{R}^n)$ to a unitary transformation in the Hilbert space $L^2(\mathbb{R}^n)$ - the Plancherel theorem: The scalar product $\langle \cdot | \cdot \rangle$ is invariant with respect to the transformation $F$; for $\varphi, \psi \in L^2$ it means: $\langle \varphi | \psi \rangle = \langle \hat{\varphi} | \hat{\psi} \rangle$. Moreover, the following important property concerning the interconnection between the convolution and the Fourier transformation is valid:

$$F(h_1 \ast h_2) = (2\pi)^n F(h_1) F(h_2) \equiv (2\pi)^n \hat{h}_1 \hat{h}_2, \quad (7.4.12)$$

with the pointwise multiplication of functions.

For the proof of our main result formulated in Theorem 7.4.8, we shall also need several following lemmas. The first one together with its proof can be deduced from [151]:

### 7.4.4 Lemma

Let $H$ be a lower-bounded selfadjoint operator on a Hilbert space $\mathcal{H}$ with its spectrum $sp(H) \geq a$. Then, for any two of nonzero vectors $\varphi, \psi \in \mathcal{H}$, it is:

(a) either $\langle \varphi | e^{-itH} | \psi \rangle \equiv 0, \forall t \in \mathbb{R}$,

(b) or $\langle \varphi | e^{-itH} | \psi \rangle \neq 0$ for $t$ in an open dense subset of $\mathbb{R}$ of total Lebesgue measure.

If the above chosen $\varphi$ is fixed, then the set of all $\psi \in \mathcal{H}$ satisfying (a) forms a closed linear subspace of $\mathcal{H}$, hence the open complement in $\mathcal{H}$ of this set contains those $\psi \in \mathcal{H}$ which satisfy the point (b).

**Proof.** Let $\lambda \mapsto E_H(\lambda)$ be the projection measure of $H$. According to the functional calculus (cf. e.g. [262]) it is

$$\langle \varphi | e^{-itH} | \psi \rangle = \int_a^\infty d\lambda e^{-it\lambda} \langle \varphi | E_H(\lambda) | \psi \rangle. \quad (7.4.13)$$

This function of time $t \in \mathbb{R}$ can be analytically continued to the lower complex half-plain of $t$, i.e. extended to $t \mapsto t - i\varepsilon =: z, \varepsilon \geq 0$:

$$\langle \varphi | e^{-i(t-i\varepsilon)H} | \psi \rangle = \int_a^\infty d\lambda e^{-i(t-i\varepsilon)\lambda} \langle \varphi | E_H(\lambda) | \psi \rangle \equiv \langle \varphi | e^{-izH} | \psi \rangle, \quad \text{Im} \ z \leq 0, \quad (7.4.14)$$

which is analytic in the open lower complex half-plain of $z$ and continuous in the closed lower half-plain, hence also on the real line $z = t - i\varepsilon \to t - i0+$. Assume that $\langle \varphi | e^{-itH} | \psi \rangle \equiv 0, \forall t \in I \subset \mathbb{R}$, where $I$ is an interval of positive length. Then, according to the Schwarz reflection principle, the analytic function $z \mapsto \langle \varphi | e^{-izH} | \psi \rangle$ is complex-analytic also on this interval $I$, hence it is identically zero also in lower complex half-plain. Due to its continuity on $\mathbb{R}$, the function $t \mapsto \langle \varphi | e^{-itH} | \psi \rangle \equiv 0 (\forall t \in \mathbb{R})$. 

In the other cases, there is no interval of nonzero length \( I \subset \mathbb{R} \) on which the function \( t \mapsto \langle \varphi|e^{-itH}\psi \rangle \) identically vanishes. Since it is continuous, it is \( \neq 0 \) on open intervals composing an open dense subset of \( \mathbb{R} \). But union of all these intervals is a set of total Lebesgue measure on \( \mathbb{R} \), as is shown in [151]. Hence the function \( t \mapsto \langle \varphi|e^{-itH}\psi \rangle \neq 0 \) a.e. with respect to the Lebesgue measure.

Linearity of the set of the \( \psi \)'s satisfying (a) is clear. That this subspace is closed in \( \mathcal{H} \) follows from the norm-continuity of the matrix elements \( \psi \mapsto \langle \varphi|e^{-itH}\psi \rangle \); the last assertion follows from the other proved assertions of this Lemma.

**7.4.5 Lemma.** The condition \( \varphi \in \mathcal{D}(\mathbb{R}^3) \) for the choice of the vector \( \varphi \) occurring in the definition of the interaction Hamiltonian in (7.4.4), as well as the condition \( \psi \in \mathcal{H}_B \cap L^1(\mathbb{R}^3) \) for the choice of the particle’s initial vector \( \psi \), both imposed in the Theorem 7.4.8, guarantee the following properties of the functions \( t \mapsto F^0_\varphi(\psi)(t) \) (7.4.6a) of the time variable \( t \in \mathbb{R} \):

\[
F^0_\varphi(\psi) \in L^2(\mathbb{R}) \cap L^1(\mathbb{R}), \quad g \equiv F^0_\varphi(\varphi) \in L^2(\mathbb{R}) \cap L^1(\mathbb{R}). \tag{7.4.15}
\]

The sets \( \mathcal{D}(\mathbb{R}^3) \), hence also \( L^1(\mathbb{R}^3) \cap L^2(\mathbb{R}^3) \supset \mathcal{D}(\mathbb{R}^3) \) are dense in \( \mathcal{H}_B \).

**Proof.** According to the Theorem IX.30 of [262], there is for \( \psi \in L^1(\mathbb{R}^3) \cap L^2(\mathbb{R}^3) \):

\[
\text{ess sup}_{x \in \mathbb{R}^3} |e^{-itH_B}\psi(x)| \equiv \|e^{-itH_B}\psi\|_\infty \leq |t^{-\frac{3}{2}}| \|\psi\|_1. \tag{7.4.16}
\]

The function \( \varphi \) has finite support, say \( \varphi(x) \neq 0 \Rightarrow |x| < R < \infty \). Let us denote by \( B_R \subset \mathbb{R}^3 \) the ball of radius \( R \) containing the support of \( \varphi \). Due to the implication \( \chi \in L^2(\mathbb{R}^3) \Rightarrow |\chi| \in L^2(\mathbb{R}^3) \), we have

\[
|\langle \varphi|e^{-itH_B}\psi \rangle| \leq \int_{B_R} d^3x |\varphi(x)| \cdot |e^{-itH_B}\psi(x)| \leq \int_{B_R} d^3x |\varphi(x)| \cdot \frac{\|\psi\|_1}{|t^{\frac{3}{2}}|} = \frac{\|\varphi\|_1\|\psi\|_1}{|t^{\frac{3}{2}}|}. \tag{7.4.17}
\]

But the matrix element of a unitary operator between two normalized vectors in \( \mathcal{H}_B \) is bounded by unity: \( |F^0_\varphi(\psi)(t)| \leq 1 \), hence we have

\[
|\langle \varphi|e^{-itH_B}\psi \rangle| \leq \min \{ 1; \frac{\|\varphi\|_1\|\psi\|_1}{|t^{\frac{3}{2}}|} \}, \text{ for all } t \in \mathbb{R}, \tag{7.4.18}
\]

and the obtained estimate is

\[
|F^0_\varphi(\psi)(t)| \leq \theta \left( (\|\varphi\|_1\|\psi\|_1)^{\frac{3}{2}} - |t| \right) + \theta \left( |t| - (\|\varphi\|_1\|\psi\|_1)^{\frac{3}{2}} \right) \frac{\|\varphi\|_1\|\psi\|_1}{|t^{\frac{3}{2}}|}. \tag{7.4.19}
\]

The function \( t \mapsto |t^{-\frac{3}{2}}| \theta(|t| - k), \ k > 0 \), belongs to \( L^1(\mathbb{R}) \cap L^2(\mathbb{R}) \), hence \( F^0_\varphi(\psi) \) also belongs there \( \forall \psi \in L^1(\mathbb{R}^3) \cap L^2(\mathbb{R}^3) \). Since also our \( \varphi \in \mathcal{D}(\mathbb{R}^3) \subset L^1(\mathbb{R}^3) \cap L^2(\mathbb{R}^3) \), the both relations in (7.4.15) are proved. The density of \( \mathcal{D}(\mathbb{R}^3) \) in \( L^2(\mathbb{R}^3) \) is easily seen, cf. e.g. [324, I.1.7].

\[\square\]
Lemma. Let $G \in L^1(\mathbb{R}^n) \cap L_0^\infty(\mathbb{R}^n)$ and $G' \in L^p(\mathbb{R}^n) \cap L_0^\infty(\mathbb{R}^n)$ $(1 \leq p \leq \infty)$, where $L_0^\infty$ is the space of (essentially) uniformly bounded functions converging to zero at infinity. Then the convolution is $G * G' \in L^p \cap L_0^\infty$.

Proof. According to the Theorem 1.3. in [298], $\|G * G'\|_p \leq \|G\|_1 \cdot \|G'\|_p$, and also $\|G * G'\|_\infty \leq \|G\|_1 \cdot \|G'\|_\infty$, hence $G * G' \in L^p \cap L^\infty$. It remains to prove the convergence to zero at infinity.

Let us choose $\delta > 0$. For any such $\delta$ there is a $T_\delta > 0$ such, that $\forall |\tau| > T_\delta \Rightarrow |G'(\tau)| < \delta$. Then for $|t| > T_\delta$ it is

$$|G * G'(t)| \leq \int_{|\tau| < T_\delta} \text{d}^n \tau |G(t - \tau)G'(\tau)| + \delta \int_{|\tau| > T_\delta} \text{d}^n \tau |G(t - \tau)|$$

$$\leq \|G'\|_\infty \Omega_n(T_\delta) \sup_{|\eta| \geq |t - \tau|} |G(\eta)| + \delta \|G\|_1,$$  

(7.4.20)

where $\Omega_n(T)$ is the Euclidean volume of the n-dimensional ball of radius $T$. With any fixed $\delta$, the supremum converges to zero with $|t| \to \infty$. Hence, by a convenient choice of $\delta > 0$ and for sufficiently large $|t|$, the right hand side of (7.4.20) can be made arbitrarily small, hence the left hand side converges with $|t| \to \infty$ to zero.

A similar useful Lemma for functions of $t \in \mathbb{R}$ restricted to $\mathbb{R}_+$ claims:

Lemma. For $h \in L^1(\mathbb{R}) \cap L_0^\infty(\mathbb{R})$ and $k \in L^1(\mathbb{R})$ it is:

$$h_+ * k_+ \in L^1(\mathbb{R}) \cap L_0^\infty(\mathbb{R}).$$  

(7.4.21)

Proof. Again from the known $L^p$-estimate [298] there is $h_+ * k_+ \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$, and also $\|h_+ * k_+\|_p \leq \|h_+\|_p \|k_+\|_1$ for $p = 1, \infty$. Let us prove the convergence to zero. It is

$$h_+ * k_+(t) = \theta(t) \int_0^\frac{1}{2} \text{d} \tau [h(t - \tau)k(\tau) + h(\tau)k(t - \tau)],$$  

(7.4.22)

and the needed estimate is:

$$|h_+ * k_+(t)| \leq \theta(t) \left[ \|k\|_1 \sup_{\tau > \frac{1}{2}} |h(\tau)| + \|h\|_\infty \int_{\frac{1}{2}}^{+\infty} \text{d} \tau |k(\tau)| \right].$$  

(7.4.23)

The first term on the right hand side converges for $t \to +\infty$ to zero because the function $h$ converges to zero. The second term converges to zero due to integrability of $k \in L^1(\mathbb{R})$. This shows that $h_+ * k_+ \in L_0^\infty$. The assertion is proved.

We shall give here a proof of the main result of this section:

Theorem. Let the dynamics of the compound system: nonrelativistic point particle $B$ (as a “detected microsystem”) and the one-dimensional spin chain $A$, described in Sec. 7.3 (as a “detector”), be given by the Hamiltonian (7.4.5) defined in the ground-state representation (corresponding to the state $\omega_A^\downarrow$ of the chain with “all spins pointing down”).
Let the particle’s initial normalized state-vector be $\psi \in \mathcal{H}_B \cap L^1(\mathbb{R}^3) \equiv L^1(\mathbb{R}^3)$, and the initial state of our half-infinite chain be $\omega^A_1$ from (7.4.2). The normalized vector $\varphi \in L^2(\mathbb{R}^3)$ occurring in the Hamiltonian $H$ in (7.4.4) will be chosen as a rapidly decreasing $C^\infty(\mathbb{R}^3)$ function with compact support: $\varphi \in \mathcal{D}(\mathbb{R}^3) \subset \mathcal{H}_B \cap L^1(\mathbb{R}^3)$. To ensure a nontrivial interaction of the particle with the chain, let us assume that (cf. Lemma 7.4.4)

$$F^0_\varphi(\psi)(t) \equiv \langle \varphi \exp(-itH_B) | \psi \rangle \neq 0, \quad t \in \mathbb{R}. \quad (7.4.24)$$

We require, moreover, a condition on the upper bound on the interaction constant $\gamma$ to be fulfilled:

$$0 < \| \gamma g \|_1 < 2, \quad (7.4.25)$$

with $g \equiv F^0_\varphi(\varphi)$.

If these conditions are satisfied, then there exist, for all $a \in \mathfrak{A}$, $b \in \mathcal{L}(\mathcal{H}_B)$, the limits

$$\lim_{t \to \infty} \omega_{AkB}^A(ab) = (w(\psi) \omega^A_1(a) + (1 - w(\psi)) \omega^A_1(a)) \omega^B_0(b), \quad (7.4.26a)$$

with $\omega_{AkB}^A(ab) \equiv \langle \psi \otimes \Omega_0 | e^{itH} a \otimes b e^{-itH} | \Omega_0 \otimes \psi \rangle$, i.e.

$$w^* - \lim_{t \to \infty} \omega_{0k}^{AkB} \circ \tau_t \equiv w^* - \lim_{t \to \infty} \omega_{tk}^{AkB} = (w(\psi) \omega^A_1 + (1 - w(\psi)) \omega^A_1) \otimes \omega^B_0. \quad (7.4.26b)$$

The probability of the detection $w(\psi)$ is here positive: $w(\psi) > 0$, and, moreover, it depends on the initial state $\psi$ of the particle as:

$$\psi \mapsto \langle \psi | W | \psi \rangle \equiv \langle \psi | W_\gamma | \psi \rangle \equiv w(\psi), \quad (7.4.27)$$

where $W \equiv W_\gamma \in \mathcal{L}(\mathcal{H}_B)$ is a positive operator $0 < W_\gamma < \mathcal{I}_{\mathcal{H}_B}$, independent of $\psi$. Moreover, for sufficiently small nonzero interaction constants $\gamma \in [-\gamma_0, \gamma_0] \subset \mathbb{R}$ it is $W^2 \neq W$, hence $W$ is not a projector.

Proof. Let us use the notation introduced in 7.4.3. We want to prove the existence of the limit (7.4.26) first. Let the state-vectors of the chain $|m\rangle$, $m = 0, 1, 2, \ldots \infty$ be defined as in (7.3.12) with $|0\rangle := \Omega_0$. The Hilbert subspace $\mathcal{K} \equiv (\mathcal{H}_A \oplus \mathcal{H}_{|0\rangle}) \otimes \mathcal{H}_B$ of the state-space of the (initial-state representation of the) compound system “the spin half-chain & the particle” generated by vectors $|m\rangle \otimes |\psi\rangle$ ($m = 0, 1, \ldots$), $\psi \in \mathcal{H}_B$, is $H$-invariant, hence also invariant with respect to the time evolution $U_t \equiv \exp[-it(H_A + H_B + \gamma V_\varphi)]$. Let $P_{\mathcal{K}}$ be the orthogonal projector onto $\mathcal{K}$. Let us define the partial isometries $P_{nm}$ in $\mathcal{K}$ by

$$P_{nm}|k\rangle \otimes |\psi\rangle = \delta_{mk}|n\rangle \otimes |\psi\rangle, \quad \text{for all } \psi \in \mathcal{H}_B, \ n, m, k = 0, 1, 2, \ldots \quad (7.4.28)$$

Let $P_n := P_{nn}$, $\forall n$. Denote also by $P_\psi$, $\psi \in \mathcal{H}_B$ ($\|\psi\|_2 = 1$), the one dimensional projector $|\psi\rangle \langle \psi|$ in $\mathcal{H}_B$. Clearly $P_0 \Omega_0^\psi = \Omega_0^\psi \equiv |0\rangle \otimes |\psi\rangle$, and for all $k, l, m, n \in \mathbb{Z}_+$ it is
\[ P_{nm}^* = P_{mn}, \quad P_{nk}P_{lm} = \delta_{kl}P_{nm}, \quad \sum_{m=0}^{\infty} P_m = P_K. \] (7.4.29)

We shall write elements \( x = a \otimes b \in \mathfrak{A} \otimes \mathfrak{B} \) as \( x = ab \) (hence also \( a \equiv a \otimes I_B, \ b \equiv I_A \otimes b \)), if a confusion would be improbable. So, we are looking for limits
\[
\overline{\omega}(x) := \lim_{t \to \infty} \omega_{A \otimes B}(t), \quad x \in \mathfrak{A} \otimes \mathfrak{B} = \mathfrak{C}.
\] (7.4.30)

We shall see that the limits (7.4.30) for \( x \in \mathfrak{A} \subset \mathfrak{C} \) are expressible in terms of \( \overline{\omega}(P_{mn}) \). The very well known Dyson equation (7.4.31) expressing the unitary evolution group \( U_t = \exp[-it(H_A + H_B + \gamma V_\varphi)] \) of a system with the interaction \( \gamma V_\varphi \) in terms of this interaction and of the free system (without interaction) evolution group \( U^0_t \) \( (t \in \mathbb{R}) \):
\[
U_t = U^0_t - i\gamma \int_0^t d\tau U^0_{t-\tau} V_\varphi U_\tau,
\] (7.4.31)
with \( U^0_t := \exp[-it(H_A + H_B)] \), will be used repeatedly in our work here. We shall work in the Hilbert space \( K \) \( (t < \infty) \). The restriction of the interaction Hamiltonian \( V_\varphi \) to the subspace \( K \) has the form
\[
P_K V_\varphi = (P_{01} + P_{10})P_\varphi.
\] (7.4.32)

Due to the commutativity of \( U^0_t \) with \( P_0 \), we obtain for \( m \neq 0 \) after the insertion from (7.4.32) into (7.4.31):
\[
P_m U_t P_0 = -i\gamma \int_0^t d\tau P_m U^0_{t-\tau} P_{10} P_\varphi P_0 U_\tau P_0.
\] (7.4.33)

For \( m = 0 \), we obtain similarly:
\[
P_0 U_t P_0 = P_0 U^0_t - i\gamma \int_0^t d\tau U^0_{t-\tau} P_{01} P_\varphi P_1 U_\tau P_0.
\] (7.4.34)

Substitution of (7.4.33) with \( m = 1 \) to this equation leads, after a linear change of integration variables, to an integral equation for \( P_0 U_t P_0 \):
\[
P_0 U_t P_0 = P_0 U^0_t - \gamma^2 \int_0^t dt' \int_0^{t-t'} d\tau U^0_{t-t'} P_{01} P_\varphi U^0_{\tau} P_{10} P_0 U_{t'} P_0.
\] (7.4.35)

Also the commutativity of \( P_\varphi \) with \( P_{mn} \) was used here. Since \( U^A_t := e^{-itH_A} \) leaves the vector \( \Omega_0 \) invariant, it is also \( P_0 U^0_t = P_0 \exp(-itH_B) \), and
\[
P_{01} P_\varphi U^0_{\tau} P_{10} = \langle \varphi | e^{-itH_B} | \varphi \rangle \langle 1 | U^A_{\tau} | 1 \rangle P_\varphi P_0 \equiv f(\tau) P_\varphi P_0.
\] (7.4.36)

The integral equation (7.4.35) can be rewritten now in the form:
7.4. PARTICLE DETECTION - A "NONIDEAL" MEASUREMENT

\[ P_0 U_t P_0 = P_0 e^{-iH_B t} - \gamma^2 \int_0^t dt' \int_0^{t-t'} d\tau e^{-i(t-t'-\tau)H_B} P_0 f(\tau) P_0 U_{t'} P_0. \]  

(7.4.37)

With the symbols from (7.4.6a) and (7.4.6b), by taking the matrix elements of both sides of this equation as in (7.4.6b), we can write the equation for \( F(t) \), cf. Notation 7.4.3:

\[ F(t) = F^0(t) - \gamma^2 \int_0^t dt' \int_0^{t-t'} d\tau g(t-t'-\tau)f(\tau)F(t'). \]  

(7.4.38a)

If we take the restrictions of these functions to the values of the argument \( t \geq 0 \) according to (7.4.9), we can rewrite (7.4.38a) as a convolution equation, cf. also (7.4.10):\(^6\)

\[ F_+ = F_0^0 - \gamma^2 g_+ * f_+ * F_. \]  

(7.4.38b)

We shall express now the quantities \( \omega^{Ak\&B}_t (P_m) \) in terms of the subsection 7.4.3, with a help of (7.4.33):

\[ \omega^{Ak\&B}_t (P_m) = \gamma^2 \int_0^t dt' \int_0^{t-t'} \bar{F}(t')F(t'')g(t-t'')\bar{f}_m(t-t')f_m(t-t''), \ m = 1, 2, \ldots \]  

(7.4.39)

To obtain a similar expression for \( \omega^{Ak\&B}_t (P_0) \) we shall use completeness of the set of projections \( \{ P_m : m \in \mathbb{Z}_+ \} \) in the subspace \( K \), cf. (7.4.29). We can sum over \( m \) in the argument of \( \omega^{Ak\&B}_t (\cdot) \) in (7.4.39) because of normality of the state \( \omega^{Ak\&B}_t \in \mathcal{S}(\mathfrak{C}) \) for finite \( t \). After the summation we can perform also \( \lim_{t \to \infty} \). Summation over \( m \) in (7.4.39) can be performed under the integral signs due to Lebesgue dominated convergence theorem, cf. the definition of \( f_m \). The completeness of the orthonormal basis \( \{|m\rangle \mid m = 1, 2, \ldots \} \) in \( \mathcal{H}_A \) gives also:

\[ \sum_{m=1}^{\infty} \bar{f}_m(t-t')f_m(t-t'') = f_1(t'-t''). \]  

(7.4.40)

We then obtain:

\[ \omega^{Ak\&B}_t (P_0) = 1 - \gamma^2 \int_0^t dt' \int_0^{t-t'} dt'' \bar{F}(t')F(t'')f(t'-t''). \]  

(7.4.41)

To see the asymptotic properties of \( \omega^{Ak\&B}_t (P_m) \ (t \to +\infty) \), we shall need some properties of the solution \( F(t) \) of (7.4.38). We shall obtain them by expressing the solution of the Volterra equation (7.4.38b) in the form of (Carl) Neumann series

\[ F_+ = \sum_{n=0}^{\infty} (-\gamma^2 g_+ * f_+ *)^n F^0_+, \]  

(7.4.42)

\(^6\)Note that, due to time-reflection symmetry of all the systems considered here, quite analogical equations and the corresponding results could be obtained also for the function \( t \mapsto F(-t), \ t \geq 0. \)
converging uniformly on any bounded interval for any γ and any continuous f, g. \(^7\) Since the free particle Hamiltonian \(H_B := \hat{p}^2\) has an absolute continuous spectrum, the functions \(F^0(t)\) and \(g(t)\) from (7.4.6a) are continuous converging to zero for \(t \to \infty\). With our assumptions it is 

\[
|f(t)| \leq 1 \Rightarrow \|f\|_1 \leq \|g\|_1 = 2\|g_+\|_1.
\]

This implies

\[
\|\gamma^2 g_+ * f_+\|_1 < \gamma^2 \|g_+\|_1 \cdot \|f_+\|_1 < 1,
\]

which is a sufficient condition for also the \(L^1\)-norm convergence of the series in (7.4.42). In this way we obtained (cf. also Footnote 6)

\[
F \in L^2(\mathbb{R}) \cap C_0(\mathbb{R}).
\]  

We conclude from the preceding that

\[
\lim_{t \to \infty} \omega^\text{A & B}_t (P_m) = 0, \quad \text{for all } m \geq 1.
\]

The corresponding limit for \(m = 0\) is obtained from (7.4.41). Written in the form of the scalar product \((\cdot, \cdot)\) \in \(\mathbb{C}\) in \(L^2(\mathbb{R})\), it has the form:

\[
\lim_{t \to \infty} \omega^\text{A & B}_t (P_0) = 1 - \gamma^2 (F_+, F_+ * f).
\]

We can prove the assertion (7.4.26) of the Theorem now. Since the space \(\mathcal{K}\) of the used representation of \(\mathcal{C}\) is time invariant with respect to our dynamics of the interacting systems, we shall restrict our work to investigation of the limits \(\lim_{t \to \infty} \omega^\text{A & B}_t (ab)\) for \(a = P_{mn}, \ m, n \in \mathbb{Z}_+,\) resp. \(a = I_{H_{\text{vac}}}, \) and \(b = |\psi_1\rangle\langle\psi_2|, \ \psi_j \in \mathcal{H}_B,\) resp. \(b = I_{H_B};\) for possibly more details cf. [38].

Let \(|\Omega_t^\psi\rangle := \exp(-itH)|0\rangle \otimes |\psi\rangle \equiv |\Omega_t(\psi)\rangle, \ |\Omega_0(\psi_j)\rangle := |0\rangle \otimes |\psi_j\rangle.\) On the basis of the following elementary estimates:

\[
|\omega^\text{A & B}_t (P_{mn}b)| \equiv |\langle P_m \Omega^\psi_t | P_{mn}b P_n \Omega^\psi_t \rangle| \leq \|b\|_1 \sqrt{\omega^\text{A & B}_t (P_m) \omega^\text{A & B}_t (P_n)}
\]

we obtain from (7.4.45)

\[
\lim_{t \to \infty} \omega^\text{A & B}_t (P_{mn}b) = 0, \quad \text{for } m + n > 0.
\]

Let us calculate now for arbitrary \(\psi_{1,2} \in \mathcal{H}_B\)

\[
\omega^\text{A & B}_t (P_0 |\psi_1\rangle \langle\psi_2|) = \langle \Omega^\psi_t |\Omega_0(\psi_1)\rangle \langle \Omega_0(\psi_2) |\Omega^\psi_t \rangle.
\]

We find, according to the notation from 7.4.3 (3.) (used now for arbitrary \(\psi', \ \psi \in \mathcal{H}_B\), and according to the equation (7.4.38), that

\[
\langle \Omega_0(\psi') |\Omega^\psi_t \rangle_+ \equiv \langle \Omega_0(\psi') |P_0 U_t P_0 |\Omega_0(\psi)\rangle_+ = F^0_{\psi'}(\psi_+)(t) - \gamma^2 F^0_{\psi'}(\varphi_+ + f_+ * F_+(t))
\]

It follows from (7.4.44) that the right hand side of (7.4.49) converges with \(t \to +\infty\) to zero, hence also the right hand side in (7.4.48) converges to zero (for all \(\psi_j\)). Hence

\(^7\)To see this, calculate \(\sum_{n=0}^{\infty} (h_+)^n(t)\) for \(h \equiv \text{const.}\)
Let us introduce the functions $G(t', t'')$ and $g(\psi_1, \psi_2)(t', t'')$ of $\{t', t''\} \in \mathbb{R}^2$:

$$G(t', t'') := \bar{F}_+(t') F_+(t'') ; \ g(\psi_1, \psi_2)(t', t'') := f_1(t'' - t') F^0_\varphi(\psi_1)(t' - t) F^0_\varphi(\psi_2)(t'' - t) \bar{f}_m(t - t') f_m(t - t'').$$

(7.4.51)

A use of (7.4.40) leads us to:

$$\omega_t^{A,B}(P_m|\psi_1)\langle \psi_2|) = \gamma^2 \int_0^t dt' \int_0^t dt'' \bar{F}(t') F(t'') F^0_\varphi(\psi_1)(t' - t) F^0_\varphi(\psi_2)(t'' - t) \bar{f}_m(t - t') f_m(t - t').$$

(7.4.52)

where $* \, \text{denotes the } 2\text{-dimensional convolution. From the given properties of the entering functions (cf.} \ \text{also our Lemma 7.4.6, and the $L^p$-estimates in \cite{262, 298})}, \ \text{and with the use of (7.4.50), we obtain the desired result:}$

$$\lim_{t \to \infty} \omega_t^{A,B}(|\psi_1\rangle\langle \psi_2|) = 0, \ \psi_j \in \mathcal{H}_B.$$  

(7.4.53)

The existence of a limit state $\overline{\omega} := w^* \lim_{t \to +\infty} \omega_t^{A,B}$ according to (7.4.26) is proved; its form as a product state (7.4.26) in $\mathcal{S}({\mathfrak{A}} \otimes \mathfrak{B})$ can be seen by checking its values on elements of $\mathfrak{A} \otimes \mathfrak{B}$, cf. also \cite{38} and \cite[1.4.5.Proposition 2]{90}. By comparing the definition in 7.4.3 of the no-particle state $\omega_0^B$ on $\mathfrak{B}$ with our results, and considering the results (7.4.45), (7.4.47), and (7.4.50) (together with (7.4.53)) we finally obtain:

$$\overline{\omega} := w^* \lim_{t \to \infty} \omega_t^{A,B} = (w \omega_A^A + (1 - w) \omega_A^B) \otimes \omega_0^B, \ \text{with} \ w := \gamma^2 (F_+, F_+ * f).$$

(7.4.54)

Let us show next that the probability $w$ in (7.4.54) is positive and has the form

$$w = \langle \psi|W_\gamma|\psi\rangle, \ \text{where} \ W_\gamma \in \mathcal{L}(\mathcal{H}_B), \ 0 < W_\gamma \neq W^2, \quad \text{where} \ \psi \in \mathcal{H}_B \ \text{is the initial state-vector of the scattered particle.}$$

(7.4.55)
Remember that the function $f$ does not depend on the initial state $\psi$ of the scattered particle, (7.4.8). The function $\psi \mapsto F(t) \equiv F_\varphi(\psi)(t)$, $\psi \in \mathcal{H}_B$ is, according to its definition (7.4.6b), a bounded linear functional of the initial state-vector $\psi$, and the same is valid for $F_+(t)$. Hence, the probability $w := w(\psi)$ in (7.4.54) is a quadratic function of $\psi \in \mathcal{H}_B$. We can rewrite it, by applying to it the **polarization identity**, into a sesquilinear form dependent on two vectors $\psi_1, \psi_2 \in \mathcal{H}_B$ being "occasionally" chosen in the expression of $w(\psi)$ to be equal: $\psi_1 = \psi_2 \equiv \psi$. So, let us write $w(\psi) =: \mathcal{W}(\psi, \psi)$, and define:

\[
\mathcal{W}(\psi_1, \psi_2) := \frac{1}{4} \sum_{\alpha = \pm i, \pm 1} \alpha w(\alpha \psi_1 + \psi_2)
\]

(7.4.56a)

which is the wanted bounded sesquilinear form on $\mathcal{H}_B$ depending on $\psi_1$ antilinearly; hence, it can be written as a matrix element of a bounded linear operator on $\mathcal{H}_B$. Let us denote this operator as $W_\gamma$:

\[
\langle \psi_1 | W_\gamma | \psi_2 \rangle := \mathcal{W}(\psi_1, \psi_2) = \frac{1}{4} \sum_{\alpha = \pm i, \pm 1} \alpha \mathcal{W}(\alpha \psi_1 + \psi_2, \alpha \psi_1 + \psi_2), \quad W_\gamma \in \mathcal{L}(\mathcal{H}_B), \quad (7.4.56b)
\]

and we can write the probability $w$ in the form of a diagonal element of $W \equiv W_\gamma$:

\[
w \equiv w(\psi) := \gamma^2(F_\varphi(\psi)_+, F_\varphi(\psi)_+ \ast f) = \langle \psi | W_\gamma | \psi \rangle, \quad \psi \in \mathcal{H}_B,
\]

(7.4.56c)

where the first bracket $(\cdot, \cdot)$ denotes the scalar product in $L^2(\mathbb{R})$, and the second one: $\langle \cdot | \cdot | \cdot \rangle$ is a matrix element in $\mathcal{H}_B = L^2(\mathbb{R}^3)$.

If we notice that the function $f$ from (7.4.8) entering (7.4.56c) is of positive type (because it is a diagonal matrix element of $\exp[-i(H_A + H_B)]$, cf. [262, Thm. IX.9], and if we reconsider the (commutative) convolution operation $f \ast$ in (7.4.56c) as a linear operator $f \ast \in \mathcal{L}(L^2(\mathbb{R}))$, we can immediately see that the operator $W_\gamma$ is a positive operator on $\mathcal{H}_B$, $W_\gamma \geq 0$. It remains to check that the matrix element $\langle \psi | W_\gamma | \psi \rangle$ in (7.4.56c) is different from zero, if the assumptions of our Theorem are fulfilled.

To proceed further, let us rewrite the expression (7.4.56c) of $w$ in terms of Fourier transforms.

Let us take Fourier transform of the equation (7.4.38b) for $F(t) = F_\varphi(\psi)(t)$. We shall use the notation:

\[
\hat{F}_+(u) \equiv \mathcal{F}(F_+(\psi)_+)(u) \equiv \mathcal{F}(\theta \cdot F_\varphi(\psi))(u),
\]

(7.4.57a)

and similarly for other functions $g_+ \mapsto \hat{g}_+$, $f_+ \mapsto \hat{f}_+$, or also

\[
\mathcal{F}(F^0_+) \equiv (F^0_+)^* \equiv \hat{F}^0_+ \equiv \mathcal{F}(F^0_+(\psi)_+)(\bullet) \equiv \mathcal{F}(\theta \cdot F^0_\varphi(\psi)).
\]

(7.4.57b)

We obtain then from (7.4.38b) the transformed equation:

---

8This notation should not be confused with $\mathcal{F}(F)_+ := \theta \cdot \mathcal{F}(F) \equiv (\hat{F})_+$, differing by the place where the sign "+" occurs.
\[ \hat{F}_+ = \hat{F}_+^0 - 2\pi \gamma^2 \hat{g}_+ \hat{f}_+ \hat{F}_+, \] (7.4.58)

which can be solved immediately:

\[ \hat{F}_+(u) = \frac{\hat{F}_+^0(u)}{1 + 2\pi \gamma^2 \hat{g}_+(u) \hat{f}_+(u)}, \quad u \in \mathbb{R}, \] (7.4.59a)

or in another form

\[ \mathcal{F}(F_+)(u) = \frac{\mathcal{F}(F_+^0)(u)}{1 + 2\pi \gamma^2 \mathcal{F}(g_+)(u)\mathcal{F}(f_+)(u)}. \] (7.4.59b)

This is the Fourier transform of the explicit expression (7.4.42) of the solution of (7.4.38) obtained with the help of Carl Neumann series.

Let us rewrite the expression (7.4.56c) for the probability \( w(\psi) \equiv \langle \psi | W_\gamma | \psi \rangle \) with the help of (7.4.59) (remember the notation (7.4.6b)):

\[ \langle \psi | W_\gamma | \psi \rangle = \gamma^2 (\hat{F}_+, \hat{F}_+ \cdot \hat{f}) = \gamma^2 \sqrt{2\pi} \int_{\mathbb{R}} du \hat{f}(u) \frac{|\hat{F}_+^0(u)|^2}{|1 + 2\pi \gamma^2 \hat{g}_+(u) \hat{f}_+(u)|^2}. \] (7.4.60)

Let us investigate properties of the above integrand in some details. Let us express first the function \( \hat{f}_+(u) = \mathcal{F}(f_1 \cdot g \cdot \theta)(u) = \sqrt{2\pi} \hat{f}_1 \cdot \hat{g}_+(u) = \sqrt{2\pi} \mathcal{F}(f_1 \cdot \theta) \cdot \hat{g}(u) \). The Fourier image \( \hat{f}_1(u) \) of \( f_1(t) \equiv \frac{1}{t} J_1(2t) \) can be obtained with a help of its integral representation taken from [129, 3.752-2]:

\[ f_1(t) = \frac{1}{t} J_1(2t) = \frac{4}{\pi} \int_0^1 \cos(2tx) \sqrt{1 - x^2} \, dx. \] (7.4.61)

We can rewrite this expression to the forms

\[
\begin{align*}
    f_1(t) & = \frac{1}{2\pi} \int_{-2}^2 e^{itu} \sqrt{4 - u^2} \, du \\
    & = \frac{1}{2\pi} \int_{-\infty}^{+\infty} e^{itu} \theta(2 - |u|) \sqrt{4 - u^2} \, du \\
    & = \left[ \mathcal{F}^{-1} \left( \frac{1}{\sqrt{2\pi}} \theta(2 - |u|) \sqrt{4 - u^2} \right) \right](t),
\end{align*}
\] (7.4.62)

hence, we obtain from (7.4.62) the wanted Fourier image immediately:

\[ \hat{f}_1(u) \equiv \mathcal{F}(f_1)(u) = \frac{1}{\sqrt{2\pi}} \theta(2 - |u|) \sqrt{4 - u^2}. \] (7.4.63)

The expression (7.4.61) of \( f_1 \) leads, in agreement with its definition (7.4.7), to the estimates

\[ |f_1(t)| \leq \frac{4}{\pi} \int_0^1 dx |\cos(2tx)| \sqrt{1 - x^2} \leq \frac{4}{\pi} \int_0^1 dx \sqrt{1 - x^2} = \frac{4}{\pi} \int_0^{\pi/2} d\alpha \cos^2 \alpha = 1, \] (7.4.64)
where we used the change of the integration variable $x := \sin\alpha$, the identity $\sin^2\alpha + \cos^2\alpha \equiv 1$, and the symmetry properties of the goniometric functions. Since both functions $f_1, g$ are continuous, $g(t) = (\varphi, \exp(-itH_B)\varphi)$, $\varphi \in \mathcal{D}(\mathbb{R}^3)$ is the Fourier image $\hat{\varphi} \in \mathcal{S}(\mathbb{R}^3)$ is an entire analytic function of three complex variables [262, Thm. IX.12], the function $t \to g(t) \neq 0$ (a.e. for $t \in \mathbb{R}$) according to Lemma 7.4.4, and the continuous function $f_1(t)$ is not constant, hence the function $|f_1(t)| < 1$ on certain intervals of $\mathbb{R}$, the estimate for $L^1$-norms gives:

$$\|f\|_1 \equiv \|f_1 \cdot g\|_1 < \|g\|_1,$$  \hspace{1cm} (7.4.65)

hence we have here obtained the sharp inequality. From the definition of the Fourier transformation it is seen that the following trivial inequality is valid for any function $h \in L^1(\mathbb{R})$:

$$\|\hat{h}\|_\infty \leq \frac{1}{\sqrt{2\pi}} \|h\|_1.$$  \hspace{1cm} (7.4.66)

These considerations give an estimate for the denominator in (7.4.60) by

$$\|2\pi \gamma^2 \hat{g}_+ \hat{f}_+\|_\infty \leq 2\pi \gamma^2 \|\hat{g}_+\|_\infty \|\hat{f}_+\|_\infty \leq \gamma^2 \|g_+\|_1 \|f_+\|_1 = \frac{\gamma^2}{4} \|g\|_1 \|f\|_1 < \frac{\gamma^2}{4} \|g\|_1^2.$$  \hspace{1cm} (7.4.67)

This proves, also due to the condition $\|\gamma g\|_1 < 2$ in (7.4.25), that the denominator of the integrand in (7.4.60) is everywhere different from zero and finite.

Another part of the integrand in (7.4.60) is the function $\hat{f} = \mathcal{F}(f_1 \cdot g) = \frac{1}{2\pi} \hat{f}_1 \ast \hat{g}$. The Fourier image of $g(t) \equiv \langle \varphi | \exp(-itH_B)\varphi \rangle$ is

$$\hat{g}(u) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} e^{-itu} \langle \varphi | e^{-itH_B} \varphi \rangle \, dt = \frac{1}{\sqrt{2\pi}} e^{-itu} \int_{-\infty}^{+\infty} e^{-it\lambda} \, d\lambda \langle \varphi | E_{H_B}(\lambda) | \varphi \rangle,$$  \hspace{1cm} (7.4.68a)

where $E_{H_B}(\lambda) \equiv E_{H_B}((-\infty, \lambda))$ is the projection-measure of the selfadjoint operator $H_B$. Because the spectrum of $H_B$ is positive (and absolutely continuous with respect to Lebesgue measure on $\mathbb{R}$), and the function $g(t)$ is proportional to the Fourier image of $\lambda \to \langle \varphi | E_{H_B}(\lambda) | \varphi \rangle$, one has

$$\hat{g}(u) = \theta(-u) \mathcal{F}(g)(u) = \sqrt{2\pi} \langle \varphi | E_{H_B}(-u) | \varphi \rangle.$$  \hspace{1cm} (7.4.68b)

This can be rewritten in the “$p$-representation”, which allows us to see better the dependence on the specific functions $\varphi$. We shall write the element of the solid angle $\phi$ in terms of the Euler angles $\theta, \varphi$ in $\mathbb{R}^3$ as $d\phi := \sin \theta \, d\theta \, d\varphi$, and the function $\hat{\varphi}(\vec{p}) \equiv \hat{\varphi}(p, \phi) \ (p := |\vec{p}|)$. It is

$$g(t) = (\varphi, e^{-itH_B} \varphi) = \int_{\mathbb{R}^3} d^3\vec{p} \varphi(\vec{p}) e^{-itp^2} \hat{\varphi}(\vec{p}) = \int_{-\infty}^{+\infty} dp \, p^2 e^{-itp^2} \int_{4\pi} d\phi |\hat{\varphi}(p, \phi)|^2,$$  \hspace{1cm} (7.4.68c)

which, after the change of variables $\lambda := p^2$, leads to

$$g(t) = \frac{1}{2} \int_{0}^{+\infty} d\lambda \sqrt{\lambda} e^{-it\lambda} \int_{4\pi} d\phi |\hat{\varphi}(\sqrt{\lambda}, \phi)|^2;$$  \hspace{1cm} (7.4.68d)

this has the form of the Fourier image of
\[ \mathcal{F}^{-1}(g)(\lambda) := \theta(\lambda) \sqrt{\frac{\pi}{2}} \sqrt{\lambda} \int_{4\pi} d\phi \, |\hat{\phi}(\sqrt{\lambda}, \phi)|^2, \]

and the Fourier image \( \hat{g} \) has now the form

\[ \hat{g}(u) = \hat{g}(u) \theta(-u) = \mathcal{F}^{-1}(g)(-u) = \theta(-u) \sqrt{\frac{\pi}{2}} \sqrt{-u} \int_{4\pi} d\phi \, |\hat{\phi}(\sqrt{-u}, \phi)|^2. \]

Similar considerations could be applied also to \( f(t) \equiv \langle \Omega_1 \otimes \varphi | \exp(-it(H_A + H_B))| \Omega_1 \otimes \varphi \rangle \); the spectrum of \( H_A \) from (7.4.1) acting on the Hilbert space \( \mathcal{H}_{\text{vac}} \) of the used representation consists of a single eigenvalue \{0\}, and of absolutely continuous part consisting of the interval \([-2, +2] \subset \mathbb{R} \), which can be seen from the Section 7.3, and from [36]. So the function \( f(t) = \langle \Omega_1 | \exp(-itH_A)| \Omega_1 \rangle \cdot \varphi \rangle = f_1(t)g(t) \) has the Fourier image \( \hat{f}(u) = (2\pi)^{-\frac{1}{2}} \hat{f}_1 * \hat{g}(u) \), which with the help of (7.4.63) and (7.4.68f) gives

\[ \hat{f}(u) = \frac{1}{\sqrt{2\pi}} \hat{f}_1 * \hat{g}(u) = \frac{1}{\sqrt{2\pi}} \int d\tau \hat{f}_1(\tau) \hat{g}(u - \tau) \]

Remember that \( \varphi \in D(\mathbb{R}^3) \), hence its Fourier image \( \hat{\varphi} \in S(\mathbb{R}^3) \) is an entire analytic function of three complex variables, so that the function \( p \mapsto \int_{4\pi} d\phi \, |\hat{\varphi}(p, \phi)|^2 > 0 \), a.e. for \( p > 0 \). Then (7.4.69) implies that \( \hat{f}(u) = 0 \) for \( u > 2 \), and \( \hat{f}(u) > 0 \) for almost all \( u < 2 \).

For checking finally the conditions of the positivity of \( w(\psi) \) from its expression (7.4.60), we have to check under which conditions it is \( |F^0_+(u)|^2 > 0, \ u \in S \subset \mathbb{R} \), for some \( S \) of positive Lebesgue measure.

Let us assume that \( F^0_+(u) \equiv 0 \) in some nonzero interval: \( u \in I \subset \mathbb{R} \). The function \( F^0_+(u) \equiv \frac{1}{\sqrt{2\pi}} \int_0^{+\infty} e^{-itu} \langle \varphi | \exp(-itH_B)|\psi \rangle \, dt \), cf. (7.4.6a), can be continued to a function analytic in the lower complex half plane \( \text{Im} \, u < 0 \) and continuous on the real axis \( \mathbb{R} \). The identical vanishing of this function on an interval \( I \subset \mathbb{R} \) would imply (with the help of the Schwarz Reflection Principle) its analyticity on \( I \), and consequent vanishing everywhere in the analyticity domain, hence also on the whole real axis (i.e. vanishing also on the boundary of the analyticity domain). The identical vanishing \( F^0_+(u) \equiv 0, \ \forall u \in \mathbb{R} \), would imply, however, the identical vanishing \( \langle \varphi | \exp(-itH_B)|\psi \rangle \equiv 0 \), which contradicts (7.4.24). This proves that, for \( \gamma^2 > 0 \) satisfying (7.4.25), it is \( \langle \psi | W_\gamma |\psi \rangle > 0 \), iff \( \psi \) satisfies (7.4.24). Since the condition (7.4.24) does not depend on the parameter \( \gamma \), the subspace of \( \mathcal{H}_B \) consisting of those vectors \( \psi \) for which it is \( \langle \psi | W_\gamma |\psi \rangle = 0 \) does not depend on \( \gamma \), hence also its orthogonal complement \( \mathcal{H}_W \subset \mathcal{H}_B \) is independent of \( \gamma \), cf. Lemma 7.4.4.

It remains to show that, at least for some values of \( \gamma \in \mathbb{R} \), it is \( W_\gamma^2 \neq W_\gamma \), i.e. that the positive operator \( W_\gamma \) is not a projector. For any nonzero orthogonal projector \( P \in \mathcal{L}(\mathcal{H}) \) there exists a subspace \( PH \equiv \mathcal{H}_P \subset \mathcal{H} \) such that for any normalized vector \( \psi \in \mathcal{H}_P \) it is \( \langle \psi | P |\psi \rangle = 1 \), and for all vectors \( \psi \) from its orthogonal complement: \( \psi \in \mathcal{H}_P^\perp \equiv \mathcal{H} \ominus \mathcal{H}_P \), it is \( \langle \psi | P |\psi \rangle = 0 \). If an operator \( W_\gamma \) would be a nonzero projector, for all the normalized vectors
\( \psi \in \mathcal{H}_W \) it would be \( \langle \psi | W_\gamma | \psi \rangle = 1 \). Such a \( \psi \) would necessarily satisfy (7.4.24), and then \( \langle \psi | W_\gamma | \psi \rangle > 0 \) for any \( \gamma \) satisfying (7.4.25).

For any given normalized \( \psi \) satisfying (7.4.24), the numerical function \( \gamma^2 \mapsto \langle \psi | W_\gamma | \psi \rangle \) expressed in (7.4.60) is continuous and monotonically increasing in a nonzero interval \( \gamma^2 \in [0, \gamma^2_0] \subset \mathbb{R} \). For an arbitrary normalized \( \psi \in \mathcal{H}_B \), it is \( \langle \psi | W_\gamma | \psi \rangle = 0 \), and it is \( 0 < \langle \psi | W_\gamma | \psi \rangle < 1 \) for all sufficiently small \(|\gamma| > 0 \) and all normalized \( \psi \in \mathcal{H}_B \). Hence, at least for sufficiently small nonzero \( \gamma \in \mathbb{R} \), it is \( \langle \psi | W_\gamma | \psi \rangle \neq 1 \) for normalized \( \psi \in \mathcal{H}_W \), so that \( W^2_\gamma \neq W_\gamma \), i.e. the positive operator \( W_\gamma \) is not a projector. The theorem is proved.

\[ \square \]

### 7.5 The X-Y chain as a measuring device

#### 7.5.1. The X-Y chain

Let us formulate first what we understand here under the “X-Y chain” (cf. [267], and also [271], [35], [107]) - a special case of the Heisenberg spin chains:

It is again a model of one-dimensional spin chain with \( C^* \)-algebra of observables \( \mathfrak{A} \) generated by spin creation-annihilation operators \( a_j^* \), \( a_j \) \((j \in \mathbb{Z})\), as it was introduced in 7.3.2. The algebra \( \mathfrak{A} \) is the \( C^* \)-inductive limit of the sequence of its local subalgebras \( \mathfrak{A}_n (n \in \mathbb{N}) \), each generated by \( a_j^* \), \( a_j \) \(|j| \leq n\). The dynamics in any subalgebra \( \mathfrak{A}_n \) is given by the local Hamiltonian \( H_n \) (without interaction with external magnetic field):

\[
H_n := \frac{\kappa}{2} \sum_{j=-n}^{n-1} (a_j^* a_{j+1} + a_{j+1}^* a_j),
\]

(7.5.1)

where \( \kappa \in \mathbb{R} \). These local Hamiltonians define the time-evolution \( (t; x) \mapsto \tau_t^{(n)}(x) \) of local elements \( x \in \mathfrak{A}_n \):

\[
\tau_t^{(n)}(x) := e^{iH_n x} e^{-iH_n}, \ x \in \mathfrak{A}_n, \ n \in \mathbb{N}, \ t \in \mathbb{R}.
\]

(7.5.2)

The evolution in the whole algebra \( \mathfrak{A} \) is obtained by taking first the limit \( n \to \infty \) in norm of \( \mathfrak{A} \) for any fixed \( t \in \mathbb{R} \) and any local \( x \in \mathfrak{A} \), and afterwards obtaining the result by the norm-continuity, extending it to all \( x \in \mathfrak{A} \):

\[
\tau_t(x) := n- \lim_{n \to \infty} \tau_t^{(n)}(x).
\]

(7.5.3)

Note that the term “X-Y model” comes from the form of the hamiltonian if it is rewritten in the terms of Pauli \( \sigma \)-matrices: \( \sigma_j^x := a_j^* + a_j, \ \sigma_j^y := i(a_j - a_j^*), \ \sigma_j^z := 2a_j^* a_j - 1 \), i.e.

\[
H = \frac{K}{4} \sum_j (\sigma_j^x \sigma_{j+1}^x + \sigma_j^y \sigma_{j+1}^y).
\]

(7.5.4)
7.5. THE X-Y CHAIN AS A MEASURING DEVICE

We shall write often \( H \) instead of \( H_n \), also without specifying the local characters of the entering algebraic elements \( x \), or \( A \in \mathfrak{A}, \ldots \), to simplify the notation and the corresponding comments; the reader could easily add the necessary specifications on his own.

We shall use the known formula to express the automorphism (7.5.3):

\[
e^{itH} Ae^{-itH} = \sum_{m=0}^{\infty} \frac{(it)^m}{m!} [H, A]^{(m)},
\]

where \([H, A]^{(0)} := A\), and higher elements are recurrently defined with a help of the commutator \([H, A]^{(1)} := [H, A] \equiv HA - AH\):

\[
[H, A]^{(m+1)} := [H, [H, A]^{(m)}].
\]

The application of (7.5.5) to norm-bounded elements \( A \) (with also \( H \hookrightarrow H_n \)) makes no principal problems, but calculations of time evolved elements in (7.5.5) of e.g. \( A \hookrightarrow a_j \) is technically complicated and it is much easier to work, instead with the spin operators \( a_j \), with elements \( b_j \in \mathfrak{A} \) satisfying the Fermi canonical anticommutation relations (CAR). This can be reached by the Jordan-Wigner transformation ([171], and also [106, Ch.3, 2]):

\[
b_j := a_j \prod_{k=-n-1}^{j-1} (1 - 2a_k^*a_k), \quad b_j^* := (b_j)^*, \quad (7.5.7)
\]

for \( |j| \leq n \). Although these elements become to be nonlocal with \( n \to \infty \), their bilinear combinations remain local, and this is sufficient for our calculations. Note also that there is the inverse transformation expressing \( a_j \) in terms of \( b_j \), which has the same form as (7.5.7) after the exchange \( a_{j,k} \leftrightarrow b_{j,k} \).

The elements \( b_j, b_k, j, k \in [-n, n] \) satisfy CAR:

\[
[b_j, b_k]_+ \equiv 0, \quad b_j b_k^* + b_k^* b_j := [b_j, b_k^*]_+ = \delta_{jk}.
\]

The local Hamiltonians \( H_n \) from (7.5.1) can be written now as

\[
H_n = \frac{\kappa}{2} \sum_{j=-n}^{n-1} (b_j^* b_{j+1} + b_{j+1}^* b_j).
\]

We can calculate now the time evolution of the elements \( b_j \in \mathfrak{A} \). We shall need later the estimates for \( \tau(t)(a_j^* a_j) \), and due to equality \( a_j^* a_j = b_j^* b_j \) the explicit expressions for \( \tau(t)(b_j) \) will be sufficient for us. We can use (7.5.5) to calculate \( \tau_t(b_j) \). One easily checks that the multiple commutators have the form:

\[
[H, b_j]^{(m)} = \sum_p c_j^{(m)}(p)b_p,
\]

where the c-number coefficients \( c_j^{(m)}(p) \) (\( m \in \mathbb{Z}_+, \quad j, p \in \mathbb{Z} \)) satisfy following recurrent relations:
\[ c^{(m+1)}(p) = -\frac{\kappa}{2}(c^{(m)}(p-1) + c^{(m)}(p+1)), \quad (7.5.11) \]

where \( c^{(0)}(p) = \delta_{0p}, \quad c^{(m)}(j-p) \equiv c^{(m)}_j(p). \)

It is seen that the coefficients \( c^{(m)}_j(p) \) depend on \( p-j \) only: they are expressible as linear combinations of the Kronecker deltas \( \delta_{j,p} \). Notice also that \( c^{(m)}(p-j) = c^{(m)}(p), \quad \forall p \in \mathbb{Z}. \) Note moreover that for each \( m \geq 0 \) only finite number of the coefficients \( c^{(m)}(j-p) \) is nonzero.

From (7.5.5) and (7.5.10) we have:

\[ \tau_t(b_j) = \sum_{k \in \mathbb{Z}} C_t(j-k) b_k, \quad (7.5.12a) \]

where

\[ C_t(r) := \sum_{m=0}^{\infty} \frac{(it)^m}{m!} c^{(m)}(r). \quad (7.5.12b) \]

The Bessel functions of the first kind \( J_r(t), \quad r \in \mathbb{Z}_+, \quad t \in \mathbb{R}, \) can be expressed by the power series:

\[ J_r(t) = \sum_{k=0}^{\infty} (-1)^k \left( \frac{t}{2} \right)^{2k+r} \frac{1}{k!(r+k)!}. \quad (7.5.13) \]

By calculation of coefficients \( c^{(m)}(r) \) in (7.5.12b) with the help of (7.5.11) and by comparison of coefficients at equal powers \( t^m \) of the variable \( t \in \mathbb{R} \) in the expressions (7.5.12b) for \( C_t(r) \) and in (7.5.13) for \( J_r(t) \), we can see that for \( r \in \mathbb{Z}_+ \) it is

\[ C_t(r) \equiv (-i)^r J_r(\kappa t). \quad (7.5.14) \]

After inserting this into (7.5.12a) (keep in mind that \( C_t(-r) = C_t(r) = (-i)^r J_r(\kappa t) \)) we obtain explicit expression for time evolution of elements \( b_j \in \mathfrak{A} \), hence the time-automorphism group \( \tau_t, \quad t \in \mathbb{R}, \) of \( \mathfrak{A} \) in terms of standard special functions \( J_r, \quad r \in \mathbb{Z}_+ \).

### 7.5.2. Interaction with a small system.

Let us use the just described X-Y spin chain to construction of an alternative “model of quantum measurement” now.

Let us represent the algebra \( \mathfrak{A} \) in a subspace of the CTPS = \( \bigotimes_{j \in \mathbb{Z}} \mathbb{C}^2_j \) (cf. 5.1.3) corresponding to the product-vector \( \Psi_0 \) defined as follows: Let the spins on our chain be well ordered and numbered by \( j \in \mathbb{Z} \). Let \( | \pm j \rangle \) be the states of the \( j \)-th spin being eigenvectors of the Pauli matrix \( \sigma^z_j \) corresponding to the up-, resp. down-orientations: \( \sigma^z_j | \pm j \rangle = \pm | \pm j \rangle \). Let then

\[ \Psi_0 := \bigotimes_{j \leq -1} | + j \rangle \otimes \bigotimes_{k \geq 0} | - k \rangle. \quad (7.5.15) \]

Let the Hamiltonian of this chain be
7.5. THE X-Y CHAIN AS A MEASURING DEVICE

\[ H_0 := \frac{\kappa}{2} \sum_{j \leq -2} (a_j^* a_{j+1} + a_{j+1}^* a_j) + \frac{\kappa}{2} \sum_{k \geq 0} (a_k^* a_{k+1} + a_{k+1}^* a_k), \]  

(7.5.16)

which is the Hamiltonian of the X-Y model without the term \((a_{-1}^* a_0 + a_0^* a_{-1})\). This chain with the Hamiltonian \(H_0\) will play for us the role of the “macroscopic (measuring) system”. The state described by the vector \(\Psi_0\) is stationary for this Hamiltonian:

\[ H_0 \Psi_0 = 0. \]  

(7.5.17)

The “measured microsystem” will be an additional 1/2-spin (i.e., it does not belong to the chain) with the interaction Hamiltonian

\[ V := P_+ \otimes \frac{\kappa}{2} (a_{-1}^* a_0 + a_0^* a_{-1}), \]  

(7.5.18)

where \(P_+\) is the projector in the state space \(\mathbb{C}^2\) of the added spin-microsystem projecting onto the state \(|+\rangle\) in which the spin “is pointing up”:\(\sigma^z |+\rangle = |+\rangle\). If we write (in microsystem’s state space \(\mathbb{C}^2\)) \(P_- := 1 - P_+\), the total Hamiltonian \(\tilde{H}\) of our compound system “micro & macro” reads:

\[ \tilde{H} = H_0 + V = HP_+ + H_0 P_-, \]  

(7.5.19)

where \(H\) is the total Hamiltonian of the X-Y model (7.5.4). Let the initial state of the compound system be

\[ \Phi_0 := \varphi_0 \otimes \Psi_0, \quad \varphi_0 := c_+ |+\rangle + c_- |\rangle, \]  

(7.5.20)

where \(\varphi_0\) is normalized: \(|c_+|^2 + |c_-|^2 = 1\), and \(|\pm\rangle\) are also normalized eigenvectors of \(\sigma^z \in \mathcal{L}(\mathbb{C}^2)\):

\[ P_\pm |\pm\rangle = |\pm\rangle, \quad P_+ P_- = 0. \]  

(7.5.21)

Since, in accordance with (7.5.17),

\[ \tilde{H}(|+\rangle \otimes \Psi_0) = |+\rangle \otimes H\Psi_0, \quad \tilde{H}(|-\rangle \otimes \Psi_0) = 0, \]  

(7.5.22)

the time evolution looks like:

\[ \Phi_t := e^{-it\tilde{H}} \Phi_0 = c_+ |+\rangle \otimes e^{-itH} \Psi_0 + c_- |\rangle \otimes \Psi_0. \]  

(7.5.23)

We shall show, similarly as in 7.3, that the pure state state vector \(\Phi_t\) of the compound system converges in the limit \(t \to \infty\) to the incoherent linear combination of two vectors, corresponding to two disjoint states of the compound system (as well as of the macrosystem-chain); hence this limit is a vector which describes a mixture of two macroscopically distinct states of the system. It is sufficient to check this assertion by calculation of the quantities

\[ \tilde{\omega}_t(a_j^* a_j) := \langle \Phi_t | a_j^* a_j | \Phi_t \rangle \quad \text{for } j \in \mathbb{Z}, \]  

(7.5.24)

\[ ^9\text{We shall omit usually in the following the tensor-product symbol \(\otimes\), according our preceding conventions.} \]
\[ \tilde{\omega}_t(a_j^*a_j) = |c_+|^2 \langle \Psi_0 | \tau_t(a_j^*a_j) | \Psi_0 \rangle + |c_-|^2 \langle \Psi_0 | a_j^*a_j | \Psi_0 \rangle; \]  
(7.5.25)

here, the automorphisms \( \tau_t \) are expressed in (7.5.12a).

It can be proved now that the limit \( \bar{\omega}(A) := \lim_{t \to \infty} \langle \Psi_0 | \tau_t(A) | \Psi_0 \rangle \), \( A \in \mathfrak{A} \), of a state from (7.5.25) exists, and the states \( \bar{\omega}, \omega_0 \in \mathcal{S}(\mathfrak{A}) \):

\[ \bar{\omega}(A) := \lim_{t \to \infty} \omega_t(A) \equiv \lim_{t \to \infty} \langle \Psi_0 | \tau_t(A) | \Psi_0 \rangle, \quad \omega_0(A) := \langle \Psi_0 | A | \Psi_0 \rangle, \quad A \in \mathfrak{A}, \]  
(7.5.26)

are mutually disjoint and macroscopically distinct. We shall prove now existence of the limits (7.5.26) in (7.5.25) for \( A = a_j^*a_j \). It is

\[ \omega_0(a_j^*a_j) = \begin{cases} 
1 & \text{for } j \leq -1, \\
0 & \text{for } j \geq 0.
\end{cases} \]  
(7.5.27)

Since according to (7.5.7) it is \( a_j^*a_j = b_j^*b_j \), we can use (7.5.12a) to obtain:

\[ \tau_t(a_j^*a_j) = \tau_t(b_j^*) \tau_t(b_j) = \sum_{r,s} \overline{C}_t(j-r) C_t(j-s) b_r^*b_s = \]  
(7.5.28)

where the products \( \prod_{n=m}^{m} B_q := 1 \) if \( m < n \). Hence

\[ \omega_0(\tau_t(a_j^*a_j)) = \sum_{r,s} \overline{C}_t(j-r) C_t(j-s) \omega_0 \left( a_r^* \left\{ \prod_{q=\min[r,s]}^{\max[r-1,s-1]} (1 - 2a_q^*a_q) \right\} a_s \right), \]  
(7.5.29)

and due to the properties (7.5.15) & (7.5.27) of \( \omega_0 \) and due to commutation properties of the \( a_j, a_k^* \) we see that the terms with \( r \neq s \) are zeros. According to (7.5.13) we have:

\[ \omega_t(a_j^*a_j) = \sum_{r=-\infty}^{+\infty} |C_t(j-r)|^2 \omega_0(a_r^*a_r) = \sum_{r=1}^{+\infty} |C_t(j+r)|^2 \]  
(7.5.30)

\[ = \sum_{r=1}^{+\infty} J_{2r}^2(\kappa t) \equiv \sum_{r=1}^{+\infty} J_{2r}^2(\kappa t). \]  
(7.5.31)

According to the known formula [180, (21.8-26)]:

\[ 1 = J_0^2(z) + 2 \sum_{k=1}^{+\infty} J_k^2(z), \]  
(7.5.31)

and due to the asymptotic behaviour of Bessel functions
7.6. RADIATING FINITE SPIN CHAIN

\[ J_m(t) \propto O(t^{-\frac{1}{2}}), \quad m \in \mathbb{Z}, \]  

we have finally

\[ \overline{\omega}(a_j^* a_j) := \lim_{t \to +\infty} \omega_t(a_j^* a_j) = \frac{1}{2}, \quad \text{for all} \quad j \in \mathbb{Z}. \]  

Returning to the formulas (7.5.24) & (7.5.25) of our main interest, we have obtained:

\[ \tilde{\omega}(a_j^* a_j) := \lim_{t \to +\infty} \tilde{\omega}_t(a_j^* a_j) = |c_+|^2 \overline{\omega}(a_j^* a_j) + |c_-|^2 \omega_0(a_j^* a_j). \]  

The last formula describes an (incoherent) mixture of two mutually macroscopically distinct, hence disjoint states \( \omega_0, \overline{\omega} \) on the \( C^* \)-algebra \( \mathfrak{A} \) of the infinite spin chain. This can be checked in the explicit way by calculating values of a macroscopic observable in the states \( \omega_0, \overline{\omega} \), e.g. of the observable constructed from (7.3.29)

\[ \gamma := \omega_{\text{av}} \lim_{N \to \infty} \frac{1}{N} \sum_{n=1}^{N} a_n^* a_n \in \mathfrak{B}(\mathfrak{A}^{**}) \subset \mathfrak{A}^{**}. \]  

According to (7.5.33) and (7.5.27), it is:

\[ \overline{\omega}(\gamma) = \frac{1}{2} \neq \omega_0(\gamma) = 0. \]  

Hence, again here, a microscopic system interacting with the macroscopic X-Y chain changed the chain’s initial state \( \omega_0 \) into a new, macroscopically distinct state \( \tilde{\omega}_\infty = |c_+|^2 \overline{\omega} + |c_-|^2 \omega_0 \). Here the probabilities \( |c_\pm|^2 \) of occurrence of the mutually disjoint states \( \omega_0, \overline{\omega} \) in the proper (resp. ‘genuine’, cf. 1.1.4) mixture \( \tilde{\omega}_\infty \) are exactly the probabilities of appearing of the states \( |\pm\rangle \) of the microsystem in its initial state \( \varphi_0 \), cf. (7.5.20). This corresponds again to the “ideal measurement”, as it was discussed in 7.1.3, 7.3.6 and 7.4.2.

7.6 Radiating finite spin chain

7.6.1. We shall present very briefly in this section, without proofs, the dynamics of a model of a large but finite system interacting with a Fermi field.\(^{10}\) The system’s initial state is stationary but unstable, as it was also the case of the models presented in the preceding sections. After an initial perturbation, the model evolves quickly into a new stationary state by simultaneous radiation of a Fermi particle, which escapes into infinity. The process is very quick in contrast to the time evolutions in the case of the models described in the previous sections 7.3, 7.4 and 7.5. The three preceding models might, however, serve as clear mathematical pictures of “quantum measurement” in the sense that the time evolution of a large system led with the time growing to infinity to the state “macroscopically different” from its initial state. The “macroscopic

\(^{10}\)The formulation and main features of the dynamics of this model were presented first time in [33]. The technical details are described in [39].
difference” between states of the system is mathematically expressed there as disjointness of the states on the $C^*$-algebra of observable quantities of the large system. The disjointness implies that if those states are represented as vectors in a Hilbert space, their mutual linear combinations do not lead to any interference (the $C^*$-algebra of observables representing all possible observations on the model system is fixed!) and such a linear combination is physically equivalent to a “proper mixture”, or “genuine mixture” (cf. 1.1.4), i.e. to a classical statistical description of an ensemble in which the individual copies of the large system are distributed between the uniquely determined ‘classical’ states under consideration. This unique decomposability to pure states on the algebra of classical (macroscopic) observables is a consequence of the fact that the states of a classical system form a simplex. This differs from “mixed” quantum states described by density matrices of standard QM of finite-size systems having multiple convex decompositions to extremal (pure) states.

Since the model of a “large” system described in this section is finite (corresponding by physical intuition to that consisting of finite number of some “elementary” or “small” subsystems, each of them described by elementary QM in separable Hilbert space $\mathcal{H}$ with the algebra of its observables coinciding with the whole $\mathcal{L}(\mathcal{H})$), there is no possibility of emergence of any disjoint states, hence there is no unambiguously defined “macroscopic difference” between some of its states.\footnote{An exception consists in possible introduction ‘by hand’ by a theoretician some ‘superselection rules’ representing a model of ‘macroscopic difference’ and forbidding interference between vectors from specific subspaces of $\mathcal{H}$, cf. e.g. [167].} Of course, the infinite size of the previous models is a mathematical idealization, and there should be some empirical possibility of distinction between “microscopic” and “macroscopic”, resp. between “quantum” and “classical”, also in ‘large but finite systems’, as it is perceived in our everyday life.\footnote{Another possibility is some, up to now not clearly specified basic change of QM, as it was most urgently proposed by Penrose in several his publications, e.g. in [236, 237, 238]; the main motivation for these reformulations of QM was some inclusion of the usually postulated “reduction of wave packet” [226], called by Penrose the “\textbf{process R}”, into the dynamics of general QM systems.}

This distinction needs not to be, however, mathematically sharp. Such a possibility was sketched in [153]: In a verbal transcription it could be, perhaps, formulated so that it would be very improbable to construct such an observation device on states of large (however finite) system, which could “see” simultaneously sufficiently many atoms of the system to be able to detect some interference phenomenon. This could be considered as a rough ‘definition’ of the notion that some set of states of the (now finite) apparatus consists of elements being pairwise ‘almost macroscopically different’ (cf. also [153]).\footnote{Let us illustrate briefly this idea on a long but finite spin-1/2 chain of the length $N$ with the $C^*$-algebra $\mathfrak{A}$ of its observables generated by the spin creation-annihilation operators $a_j, a_j^* \ (j = 1, 2, \ldots, N)$ acting on the finite dimensional Hilbert space $\mathcal{H}_N := (\mathbb{C}^2)^N$: If we are able to use apparatuses detecting the observables of this chain occurring in an arbitrary of the $C^*$-subalgebras $\mathfrak{B} \subset \mathfrak{A}$ generated by any of the fixed restricted set of operators $a_{jm}, a_{jm}^* \ (m = 1, 2, \ldots, K \ll N, \ 0 \leq j_m \leq N)$ only, then the states $|\Psi\rangle, |\Phi\rangle$ from $\mathcal{H}_N$ for which it holds $\langle \Psi | B | \Phi \rangle \equiv 0 \ \forall B \in \mathfrak{B}$ could be considered as ‘almost macroscopically different’, resp. ‘empirically disjoint’. This happens, e.g., if in the state $|\Psi\rangle$ all the spins are ‘pointing up’, and in the state $|\Phi\rangle$ all the spins are ‘pointing down’.} To proceed in these considerations, one would need to build some (more) general theory of observational devices. E.g., as far as
the present author knows, there were no published works paying attention to the fact that human observers come into contact with measuring apparatuses by electromagnetic interactions, and probably only by them. Shortly, according to the point of view proposed here: The formalized set of ‘observables’ of any physical system should depend on the existing possibilities of the construction of measuring devices in accordance with physical laws and environmental conditions.

We have not stressed up to now, however, that the spin chain of our present model is also coupled to a Fermi particle (resp. to the Fermi field) representing a sort of ‘environment’. The particle occurs in the initial state of the system in its vacuum state, and afterwards is radiated by the chain and subsequently escapes into infinity; the state of the Fermi field containing the radiated particle is in each finite time orthogonal to its vacuum state. This facilitates, in the intuitive sense of some sort of a ‘decoherence program’, cf. e.g. [343, 347, 124, 279], the possibility of interpretation of the effective absence of interference between the initial and final states of the spin chain in our model, as representing the two different ‘macroscopically’ distinguished ‘pointer positions’.

We shall keep in mind such an idea to be able to believe that also our finite system described in this section can be considered as a model of “quantum measurement” process.

7.6.2. Let us look at the Quantum Domino from Section 7.3. We shall restrict here that model to finite number of degrees of freedom, hence the spin chain will be of finite length and its algebra of observables $\mathfrak{A}$ (with unity $I_3$) is generated by the spin-1/2 creation and annihilation operators $a^*_j$, $a_j$ ($j = 0, 1, \ldots, N$) satisfying (7.3.1). This system will interact with the (nonrelativistic scalar) Fermi field, the algebra $\mathfrak{A}_F$ (with unity $I_3$) of which is generated by the particle creation-annihilation operators $b^*(\varphi)$, $b(\varphi)$ satisfying the relations

$$b(\varphi)^2 = 0, \quad b(\varphi)b^*(\psi) + b^*(\psi)b(\varphi) = (\varphi, \psi)I_3, \quad (\text{for all } \varphi, \psi \in L^2(\mathbb{R}^3, d^3x)), \quad (7.6.1)$$

with the linear dependence $\psi \mapsto b^*(\psi)$.

The dynamics is given by the Hamiltonian $H := H_0 + V$, where

$$H_0 := \left( \sum_{n=0}^{N-2} a^*_n a_n (a^*_{n+1} a_{n+1} + a_{n+1} a^*_{n+1} - \varepsilon_0 a^*_n a_n) \right) \otimes I_3 + I_3 \otimes d\Gamma(h), \quad (7.6.2a)$$

$$V := v^2 \left( a^*_{N-1} a_{N-1} a^*_N \otimes b^*(\varphi) + a^*_N a_{N-1} a_N \otimes b(\varphi) \right). \quad (7.6.2b)$$

We can consider these algebras $\mathfrak{A}$ and $\mathfrak{A}_F$ as algebras of operators acting on the Hilbert spaces $H_S := (\mathbb{C}^2)^{N+1}$, and the Fermi Fock space $H_F$ respectively, resp. on their tensor product $H := H_S \otimes H_F$. In the above written formulas, the symbol $d\Gamma(h)$ means the “second quantization” (cf. [54, Sec. 5.2.1]14) of the operator $h \in \mathcal{L}(\mathfrak{h}) := \mathcal{L}(L^2(\mathbb{R}^3, d^3x))$ given by the

$$d\Gamma(h)P_- \otimes_{k=1}^n \psi_k := P_- \sum_{j=1}^n \psi_1 \otimes \psi_2 \otimes \cdots \otimes \hbar \psi_j \otimes \cdots \otimes \psi_n \text{ for all } n \in \mathbb{Z}_+.$$
function \( p \mapsto \varepsilon(p) \) of one-particle momentum \( p \), hence acting on the vectors of \( \mathfrak{h} := L^2(\mathbb{R}^3, d^3x) \) “in the p-representation” as multiplication by \( \varepsilon(p) : (\psi)(p) \equiv \varepsilon(p)\psi(p) \). The nonnegative function \( \varepsilon(p) \), as well as the parameters \( \varepsilon_0 > 0, v \in \mathbb{R}, \sigma \in L^2(\mathbb{R}^3, d^3x) \), will be specified later. In our expressions of action of elements of \( \mathfrak{A} \), resp. \( \mathfrak{F} \), on vectors of \( \mathcal{H}_S \otimes \mathcal{H}_F \), the unity operators of the other algebra will be usually omitted, e.g. for \( a \in \mathfrak{A} \), \( |s\rangle \otimes |\varphi\rangle \in \mathcal{H}_S \otimes \mathcal{H}_F \), we shall write \( a \otimes I_{\mathfrak{F}}(|s\rangle \otimes |\varphi\rangle) \equiv a(|s\rangle \otimes |\varphi\rangle) \equiv a|s\rangle \otimes |\varphi\rangle \).

Let \( \Omega_0^F \) be the Fermi vacuum in \( \mathcal{H}_F \), and \( \Omega_0^S \in \mathcal{H}_S \) be the state of the spin chain “with all spins pointing down”: \( a_n\Omega_0^S = 0, \forall n \). Notice also that here \( |n\rangle \equiv a_0^*a_1^*...a_n^*\Omega_0^S, n = 0,1,...N \). Let the Hilbert subspace \( \mathcal{H}_1 \subseteq \mathcal{H} \) be generated by the vectors

\[
\{ \Omega_0 := \Omega_0^S \otimes \Omega_0^F, \beta_n := |n\rangle \otimes \Omega_0^F, \beta_N(\psi) := |N\rangle \otimes \beta^*(\psi)\Omega_0^F; n = 0,1,...N-1, \psi \in L^2(\mathbb{R}^3, d^3x) \}.
\]

Then it is valid:

**7.6.3 Lemma.** The space \( \mathcal{H}_1 \) defined above is \( H \)-invariant: \( H\mathcal{H}_1 \subseteq \mathcal{H}_1 \).

A proof of this Lemma is presented in [39]. Hence the description of our process can be restricted to time evolution in the subspace \( \mathcal{H}_1 \subseteq \mathcal{H} \). We shall choose the parameters of the model, namely the operator \( h \) acting on \( L^2(\mathbb{R}^3) \), and the quantities \( \varepsilon_0 > 0, v \in \mathbb{R}, \sigma \in L^2(\mathbb{R}^3, d^3x) \), so that with our Hamiltonian given by (7.6.2a) the relation

\[
\lim_{t \to \infty} \langle \beta_n| e^{itH}a_N^*a_N e^{-itH}|\beta_n \rangle = 1, \quad n = 0,1,...N-1,
\]

or more specifically:

\[
\langle \beta_n| e^{itH}a_N^*a_N e^{-itH}|\beta_n \rangle = 1 - o(t^{-m}), \quad n = 0,1,...N-1, \text{ for } t \to +\infty, \forall m \in \mathbb{N},
\]

will be satisfied. The meaning of (7.6.3) is that the probability of emission of the Fermi particle and simultaneous transition of the spin chain to the stationary state \( \beta_N \) (i.e. all the spins in the chain “are pointing up” and the Fermi field is again in its vacuum state) approaches certainty ‘almost exponentially quickly’ if the time is growing to infinity.

The dynamics is investigated by a repeated use of Fourier transform \( \mathcal{F} \), e.g. in [39, Lemma 2]:

**7.6.4 Lemma.** Let \( e^{-itH} \) be any (unitary) time evolution group. Then the Fourier transform of its (truncated) matrix elements for given \( \phi, \psi \in \mathcal{H} \) is

\[
\mathcal{F}[\theta(t)\langle \phi, e^{-itH}\psi \rangle](\xi) = \frac{i}{\sqrt{2\pi}} \langle \phi, R_H(\xi)\psi \rangle,
\]

for \( \xi \in \mathbb{C} : \text{Im } \xi < 0 \).

The function \( \theta \) is here the Heaviside function, and \( R_H(\xi) \equiv (H - \xi I)^{-1} (\xi \in \mathbb{C}, \xi \notin \text{sp}(H) \equiv \text{spectrum of } H) \) is the resolvent of the operator \( H \).

Another useful result is that we obtain the resolvent \( R_H(\lambda) \) as a solution of an operator equation, [39, Lemma 3].
7.6.5 Lemma. Suppose \( H = H_0 + V \in \mathcal{L}(\mathcal{H}) \) and \( \xi \notin \sigma(H) \cup \sigma(H_0) \). Then the resolvent \( R_H(\xi) \) is the solution of the operator equation

\[
R_H(\xi) = R_{H_0}(\xi)(I - VR_H(\xi)). \tag{7.6.5}
\]

Hence, the Fourier transform of the (truncated) matrix elements of the time evolution operator for \( \text{Im} \xi < 0 \) is given by:

\[
\mathcal{F}[\theta(t)\langle \phi, e^{itH} \psi \rangle](\xi) = i \sqrt{\frac{2}{\pi}} \text{Im} \langle \phi, R_{H_0}(\xi)\psi \rangle - i \sqrt{\frac{2}{\pi}} \langle \phi, R_{H_0}(\xi)VR_H(\xi)\psi \rangle. \tag{7.6.6}
\]

Important for the following analysis are the matrix elements

\[
F_{mn} := \langle \beta_m, R_H(\xi), \beta_n \rangle, \tag{7.6.7}
\]

since e.g.:

\[
\mathcal{F}[\theta(t)\langle \beta_m, e^{itH} \beta_n \rangle](\xi) = i \sqrt{\frac{2}{\pi}} F_{mn}(\xi). \tag{7.6.8}
\]

Now, the proper choice of the parameters of the model is, according to [39]:

\[
\varepsilon(p) := a|p|^2, \quad a > 0, \tag{7.6.9a}
\]

\[
\mathcal{F}(\sigma)(p) = 0 (|p| < b), \quad \mathcal{F}(\sigma)(p) > 0 \text{ for all } |p| > b > 0, \quad \sigma \in \mathcal{S}(\mathbb{R}^3), \tag{7.6.9b}
\]

\[
\varepsilon_0 > ab^2 + 2, \tag{7.6.9c}
\]

where \( \mathcal{S}(\mathbb{R}^3) \) is the set of all rapidly decreasing Schwartz complex valued functions on \( \mathbb{R}^3 \), the symbol \( \mathcal{F}(\sigma) \) again means the Fourier transform (i.e. the transition to “p-representation”), and the constants \( a, b \) occurring in (7.6.9c) are the same as the ones occurring in (7.6.9a) and (7.6.9b).

After making this choice it is possible, after a series of considerations and calculations [39], to show that (cf. [39, (4.33)])

\[
\mathcal{F}[\langle \beta_m, e^{itH} \beta_n \rangle](p) = -\sqrt{\frac{2}{\pi}} \lim_{\nu \to 0^+} \text{Im} F_{mn}(p - i\nu) \in \mathcal{S}(\mathbb{R}). \tag{7.6.10}
\]

But the Schwartz set \( \mathcal{S}(\mathbb{R}) \) of rapidly decreasing smooth functions is invariant with respect to the Fourier transform, hence the function \( t \mapsto \langle \beta_m, e^{itH} \beta_n \rangle \) also belongs to \( \mathcal{S}(\mathbb{R}) \), what proves the ‘almost exponential decay’ in time of this matrix element. This result is crucial for the proof of Theorem 7.6.6.

To formulate the main result as a theorem, let us introduce also the notation:

\[
\mu((-\infty, \lambda]) := \int_{\varepsilon(p) < \lambda} |\mathcal{F}(\sigma)(p)|^2 d^3p, \tag{7.6.11a}
\]

\[
\rho_\mu(\lambda) := \frac{d\mu((-\infty, \lambda])}{d\lambda}. \tag{7.6.11b}
\]
7.6.6 Theorem. In the above described model of finite spin chain QD interacting with nonrelativistic scalar Fermi field, with the parameters specified in (7.6.9), for either all such \( \varepsilon_0 \) with possibly one exception, or for all \( \varepsilon_0 > 2 + ab^2 + 2v^2 \int_{ab}^\infty \frac{\rho_n(\lambda)}{\lambda - ab^2} \, d\lambda \), the time evolution of the probability of all the \( N + 1 \) spins being turned up (realizing the wanted final state of the spin chain), if initially the Fermi field was in the vacuum state and the first \( n \) spins \( (N - 1 \geq n \geq 0) \) were turned up, approaches unity almost exponentially fast, i.e. the relation:

\[
\langle \beta_n | e^{itH} a_N^* a_N e^{-itH} | \beta_n \rangle = 1 - o(t^{-m}), \quad \text{for all } 0 \leq n \leq N - 1, \quad \text{for any } m \in \mathbb{N},
\]

(7.6.12)
is satisfied.

A detailed proof of this theorem can be found in [39].

7.6.7. Let us look at the result (7.6.12) from the point of view of the Section 7.7, to make it more intuitive as a relevant assertion with respect to the “measurement problem”, cf. (7.7.2).

As the “measured system” in this model can be considered the single spin lying at the ‘beginning’ of the spin chain. Let its \( C^* \)-algebra of observables be generated by \( \{a_0^*; a_0\} \) satisfying (7.3.1), and let \( \varphi_\downarrow, \varphi_\uparrow \) be its normalized state vectors corresponding to the two opposite orientations of the spin. Let its initial normalized state vector be \( \varphi_0 := c_\downarrow \varphi_\downarrow + c_\uparrow \varphi_\uparrow \), with \( a_0^* \varphi_\downarrow = \varphi_\uparrow, \quad a_0 \varphi_\uparrow = \varphi_\downarrow \).

The initial state of the whole composite system \( \{\text{measured system} \& \text{rest of the spin chain} \& \text{Fermi field}\} \) is then \( \tilde{\Psi}_0 := c_\downarrow \Omega_0 + c_\uparrow \beta_0 = (c_\downarrow I_A + c_\uparrow a_0^* )\Omega_0^S \otimes \Omega_0^F \). The time evolved states \( \tilde{\Psi}_t := \exp(-itH)\tilde{\Psi}_0 \) can be written, due to the Lemma 7.6.3 as well as the stationarity of \( \Omega_0 \), in the form

\[
\tilde{\Psi}_t = c_\downarrow \Omega_0 + c_\uparrow e^{-itH} \beta_0.
\]

(7.6.13)
The second term in (7.6.13) can be written, again due to the \( H \)-invariance of \( \mathcal{H}_1 \), cf. Lemma 7.6.3, in the form

\[
e^{-itH} \beta_0 = \sum_{n=0}^{N-1} d_n(t) \beta_n + \beta_N(\psi(t)).
\]

(7.6.14)Since \( a_N \beta_n = 0, \quad (n = 0, 1, \ldots N - 1) \), and \( a_N^* a_N \beta_N(\psi) = (1 - a_N a_N^*) \beta_N(\psi) = \beta_N(\psi) \), the expression from (7.6.12) with our \( n = 0 \) is

\[
\langle \beta_0 | e^{itH} a_N^* a_N e^{-itH} | \beta_0 \rangle = \|a_N e^{-itH} \beta_0\|^2 = \|\beta_N(\psi(t))\|^2,
\]

(7.6.15)and this converges very quickly, according to (7.6.12), to unity. The vectors on the right hand side of (7.6.14) are mutually orthogonal and the whole right hand side has the constant norm
equal to 1. Hence the norm of the sum on the right hand side of (7.6.14) quickly converges to zero. All the vectors $\beta_N(\psi) (\psi \in L^2(\mathbb{R}^3, d^3x))$ describe the states of the composite system:

\{the measured system & the rest of the spin chain & the Fermi field\}

in which all the $N+1$ spins “are pointing up”, which has to mimic the macroscopically different state from the initial state $(c_\downarrow I_3 + c_\uparrow a_0^*)\Omega_0^S \otimes \Omega_0^F \equiv (c_\downarrow I_3 + c_\uparrow a_0^*)\Omega_0$, as well as from $\Omega_0$, of the compound system. For the wave function (7.6.13) of the compound system we obtain asymptotically for large times $t \to \infty$:

$$\tilde{\Psi}_t = c_\downarrow \Omega_0 + c_\uparrow e^{-itH}\beta_0 \cong c_\downarrow \Omega_0 + c_\uparrow \beta_N(\psi(t)), \quad (7.6.16)$$

which has the form of the formula (7.7.2) for the (approximate expression of the) “measurement dynamics” in the conventional QM framework of considering of only finite systems (as measuring apparatuses). The probabilities of the two different “measurement results” corresponding to the states $\varphi_\downarrow$, resp. $\varphi_\uparrow$, occurring in the orthogonal decomposition of the initial state $\varphi_0$ of the measured system are, as it was expected, the numbers $|c_\downarrow|^2$, resp. $|c_\uparrow|^2$. By ‘tracing out’ the states of the environment $\equiv$ the Fermi field we obtain the density matrix for the spin chain, and by tracing out the both {Fermi field & the spins 1,2,..,N} we obtain the density matrix $\rho := |c_\downarrow|^2 P_{\varphi_\downarrow} + |c_\uparrow|^2 P_{\varphi_\uparrow}$, with $P_{\varphi_\downarrow} \equiv a_0^* a_0$ and $P_{\varphi_\uparrow} \equiv a_0 a_0^*$, in the state space of the measured system (i.e. of the spin placed in the point 0 of the chain), corresponding formally to the ‘collapse of its wave packet’ $\varphi_0 := c_\downarrow \varphi_\downarrow + c_\uparrow \varphi_\uparrow$, i.e. of its initial state of the just described process. Neither of these density matrices can be, however, interpreted as describing a ‘proper’, or ‘genuine’ probability distribution of quantal states in the sense of classical statistics. To interpret them in that sense, and distinguish one decomposition of a density matrix as ‘more relevant’ (i.e. reflecting the classical-type statistics), some another additional assumption is needed. We have had in our interpretations of the infinite models in previous Sections the requirement of disjointness of mutually noninterfering states, and this was ensured by existence of a macroscopic quantity obtaining mutually different values in these states. For some alternative approaches, we could go back again to the attempts in the ‘decoherence programs’, [343, 347, 124, 279]. More detailed mathematical and interpretational considerations on decompositions of states of a $C^*$-algebra can be found in our 1.2.3, 1.3.3, 1.3.4, 1.4.3, and citations therein, e.g. [53, Chap.4].

7.6.8. Notes on irreversibility. This model of a radiating multispin system can be also considered as a caricature reflecting one of the usual mechanisms of irreversible behaviour of large physical systems: Large systems usually (resp. ‘almost always’) are not isolated from their environment, and their interaction with (a ‘relative stable’, and a ‘relative stationary’) environment leads to their motion to more stable stationary, e.g. thermodynamic equilibrium, states. Some kind of radiation, as it was built in into our model, is a usual form of interactions of large systems with their environment.

This approach reflects just one ‘aspect’ of irreversible behaviour of physical systems. Another often discussed ‘aspect’ of theoretical descriptions of irreversible behaviour of finite many-particle systems is their complicated mechanical motion even if they are isolated from any
environment. Then we are dealing with such phenomena as various types of “chaos”, and with “recurrences” in their (deterministic and time-reversible) mechanical motion. We shall not consider here such mechanical explanations of irreversibility, initiated by J. C. Maxwell and L. Boltzmann. As concerns some study on these topics in the case of classical systems, it might be interesting to look to nice conference or journal papers like, e.g. [332], but more elementary and also more complex information could be found in some books on the “theory of dynamical systems” listed in our Bibliography, e.g. [1, 7, 9, 10, 181, 326, 248]. However long are durations of the Poincaré cycles corresponding to the above mentioned recurrences in mechanical motions of isolated systems with several degrees of freedom (they are comparable with the lifetime of Universe [332]), an evolution during which the system approaches some stable stationary state cannot be reached in theoretical description of finite isolated mechanical systems. This does not exclude, however, effectiveness of the statistical physics, which does not deal with a unique phase-space trajectory of the considered system; here we have a certain physical reinterpretation of the mechanics of motions in the system’s phase space. But full effectiveness of the statistical approach to description of behaviour of multiparticle systems, e.g. mathematically clear description of thermal equilibria and phase transitions, is again possible in the ‘thermodynamical limit’ of infinitely large systems only, e.g.[271].

It is seen that after making the finite quantum spin chain of our model to become an “open system” by adding to the Hamiltonian of the restricted QD the term corresponding to the radiation of a fermion, the speed of the motion to the limiting state was enormously increased in comparison with the infinite, but isolated, QD-chain, cf. (7.3.24) and (7.3.26b), i.e. with respect to (7.3.27). The finite-sized version of the isolated QD would behave, however, almost-periodically, cf. (7.3.23). The addition of interaction of the finite QD with Fermi field enabled us to obtain a system’s state converging for \( t \to \infty \) to a new stationary state. But a clear and unambiguous interpretation of some states of a finite system, e.g. the two states appearing in the sum on the right hand side of (7.6.16), as being approximately ‘mutually macroscopically different’ (hence their quantum interference being ‘almost impossible’), is still open to discussion. We shall not further investigate here some other connections of these phenomena and questions.

7.7 On the “measurement problem” in QM

Let us add here several notes to the above mentioned “measurement problem”, considered for a long time to be a fundamental problem of the conceptual structure of QM, cf. e.g. [63], [236, 237] and [238, Ch. 29]. These notes should be also supplemented by the notes in 7.6.1, esp. by the footnotes 12 and 13.

States of the physical systems are described in the mathematical theory of QM by mathematical objects like “wave functions”, “density matrices”, or “linear functionals \( \omega \) on algebras of observable quantities” (which generalize the former two classes of objects). The “observable quantities” (represented by operators, resp. elements of an algebra) correspond to experimental, or observational, arrangements of empirical situations, in which the observer is able, after “installing” a specific state \( \omega \) of the observed system, to perceive and appreciate by his human
senses some well determined, in advance expected feelings (optical, auditory, acquired by touch or in another way) of some specific perceptions that are clearly distinguishable from others (e.g. when reading positions of a pointer, or hearing a characteristic sound from a counter, . . .), so that they can be formalized into a form suitable for further communication. A single observable $A$ of a specific physical system appears in such an empirical situation through a specific instance of a set of such clearly distinguishable phenomena, each of which can be (and, as a rule, is) denoted by a number $\alpha_j (\in \mathbb{R})$ called the result of single measuring act in the state $\omega$ of a value of $A$ (not to be confused with “the value of $A$ in $\omega$” – different single measuring acts of the same observable on $\omega$ could lead to different results!). Many experiments on microscopic systems performed in the history of microphysics have shown that we are not able to prepare states of any microsystem in such a way that in a many times repeated measurement of an observable on the same (prepared each time anew) state $\omega$ one obtains the same measured value for each observable which can be chosen for these repeated measurements. To state it briefly: For any state of any microsystem there is some observable which does not have any specific value in that state. This is reflected mathematically in, e.g., Heisenberg uncertainty relations. On the other hand, to each value $\alpha_j$ of the given observable $A$ there exists (for observables with discrete spectra) at least one state $\omega_j$ such that the repeated measurements of $A$ on it give with certainty the same value $\alpha_j$. The problem arises because there is (with certainty) some other observable $B$ such that the repeated measurements of it on the same state $\omega_j$ give mutually different values $\beta_k \neq \beta_l \cdots \in \mathbb{R}$, i.e. the statistical dispersion of the measured values of $B$ in that $\omega_j$ is nonzero. Sharp values (obtained consistently in the identical, many times repeated measurements) $\beta_k$ of $B$ can be obtained in other states $\omega'_k$, for which, however, the measurements of some other observables $A, C, \ldots$ would have nonzero dispersions.

The existing very successful mathematical model of QM provides solution of this problem which consists in describing an arbitrarily chosen (but, by assumption, “pure”) state $\omega_j$ as a linear superposition of some (again pure) states $\omega'_k, \omega'_l, \ldots$, i.e., if we express all the states in the form of vectors in a Hilbert space $\mathcal{H}$, in writing the state in question as $\psi_j = \sum_k c_k \varphi_k$, where the correspondence with the values of the observables $A, B, \ldots$ described now as linear operators on $\mathcal{H}$, is such that the “state-vector” $\psi_j$, corresponding to the state $\omega_j$, is an “eigenvector” of the operator $A$ (a common practice is to use the same symbol for the operator as for the physical quantity represented by it): $A\psi_j = \alpha_j \psi_j$, and similarly the vectors $\varphi_k$ corresponding to the states $\omega'_k$ are the eigenvectors of the operator $B$: $B\varphi_k = \beta_k \varphi_k$.

All this is, of course, very well known, and we have also briefly described it in our Sec.1.2. We recall it here to stress the unusual intuition required when dealing with the phenomena described by the mathematical model of QM, in comparison with the intuition provided by the ‘everyday life’, whose formal reflection is contained in the mathematical models of classical physics.

One of the prominent results of the history of observations and measurements mentioned above is that QM is considered an irreducibly statistical theory; i.e., that the probabilistic results of the measurements with nonzero dispersions are not necessarily due to the presence of some statistical ensembles of systems in various states, as they are in the classical statistical physics, but that it is impossible to find any fully dispersionfree states even when considering individual (micro)systems. This is now (starting from 1920’s) acceptable and included in a logically
consistent manner into the description of our world. The resulting picture of the world is, however, not without problems, since its integral part is a class of counterintuitive phenomena encountered in QM. These are, pictorially expressed, the problems of the type of the well known “Schrödinger’s cat paradox”, which is just a popular representation of the “measurement problem” to be discussed further (the cat can be regarded here also as a measuring device).

We are measuring with some macroscopic apparatuses which belong to the same world as microsystems do, but seem to be correctly described by a theory that is very different from QM. Is QM a universal theory, or is there some borderline between the two differently behaving parts of the world? If so, it should be explained in the theory where that borderline is located. But the apparatuses are composite of many microsystems and (as far as the present author knows) no new aspect of microsystems was discovered which could effectively distinguish between them and macrosystems. Thus, let us regard the apparatuses as some quantum-mechanical systems. Then any measuring process should look as follows:\(^{15}\)

If the initial state of the measured microsystem is described by the normalized vector \(\varphi_k\) corresponding to the value \(\beta_k\) of the observable \(B\), and the initial state of the apparatus capable to measure the quantity \(B\) is described by the normalized vector \(\Psi_0\) in its Hilbert space, installed independently of the measured state, then the unitary process \(U(t)\) corresponding to the time evolution of the mutually interacting measured microsystem and apparatus will lead, after the ‘time of the measurement’ \(t_m\), to the state

\[
U(t_m) [\varphi_k \otimes \Psi_0] = \tilde{\Psi}_k.
\]

(7.7.1)

Here, in the ‘post-measurement state’ \(\tilde{\Psi}_k\) of the compound system microsystem & apparatus, the “pointer position” of the apparatus corresponds to the value \(\beta_k\) of \(B\). This is assumed to be valid for all \(\beta_k\), hence for \(\beta_k \neq \beta_j\) the pointer positions (i.e. certain macroscopic parameters) in the states \(\tilde{\Psi}_k\) and \(\tilde{\Psi}_j\) are different from each other. The same unitary evolution should lead, after the measurement by the same apparatus on the state \(\psi := \sum_k c_k \varphi_k\), due to its linearity, to the state of the compound system

\[
U(t_m) \left[ \left( \sum_{k \in J} c_k \varphi_k \right) \otimes \Psi_0 \right] \equiv \tilde{\Psi} := \sum_k c_k \tilde{\Psi}_k, \quad \sum_{k \in J} |c_k|^2 = 1.
\]

(7.7.2)

The ‘macroscopic part of the world’ appears here in the state \(\tilde{\Psi}\), expressed as a nontrivial linear superposition \(\tilde{\Psi}\) of the states \(\tilde{\Psi}_k\) corresponding to different values of some macroscopic parameter (different “pointer positions”, distinguished here by the index \(k\)). Such superpositions in QM do not mean only a probability distribution with nonzero dispersion of the values of a macro-parameter corresponding to various \(\beta_k\), but they should also allow (according to the principles of QM) a realization of measurements of some new observable having a sharp value in the state \(\tilde{\Psi}\) (on the statistical ensemble of equally prepared compound systems obtained in the process of the measurement of this new observable on the microsystem). The states \(\tilde{\Psi}\) are representing in such a way an interference of different values of a macro-parameter (‘the

\(^{15}\)We will work here with pure states (resp. vector states) only. In fact, it is not necessary to use density matrices in an analysis of the process of measurement in QM, as shown, e.g. by Wigner in [339].
cat is simultaneously dead and alive'). Thus, the apparent conceptual problem of QM does not consist in its probabilistic nature, it rather consists in the unanswered question of the existence of the very counterintuitive “macroscopic interference” we have just described, or/and in a dynamical explanation why they do not occur.

The widely accepted ‘solution’ of this “measurement paradox” (as termed by Penrose [238]) consists in accepting of so called “reduction postulate”, consisting in the claim that there supposedly exists the phenomenon colloquially termed the “reduction (or also collapse) of the wave packet”. This can be rephrased, in terms of our preceding considerations, in such a way that within some final phase of the process of measurement, either during or just after the measurement (e.g. such as is sketched in (7.7.2)) performed on the system, the system (i.e. either the measured system alone – this is the traditional point of view, or the apparatus, or – which seems to the present author as the most acceptable possibility – the compound system microsystem & apparatus) ends after each single run of the measurement in a specific state corresponding to the obtained value of the measured observable, and after many times repeated ‘identical’ measurements on such a state we arrive at a statistical mixture (in the sense of classical statistical physics, i.e. the “proper” or “genuine” mixture, cf. in 1.1.4) of the set of (systems occurring in the) states which, in the case of compound system, consists of

\[ \{ \tilde{\Psi}_k : k \in J \} \text{ with probabilities } |(\tilde{\Psi}, \tilde{\Psi}_k)|^2 = |c_k|^2, \quad k \in J. \]  

(7.7.3)

This transition from superpositions to classical mixtures of states with different “pointer positions” takes place, according to the reduction postulate, instantaneously, or in some “negligibly short time”.

Many existing theories of quantum measurements which have appeared up to the present day analyze systematically possible results of various measurements (of corresponding observables) as well as their mutual relations like their mutual consistency or ‘complementarity’, see e.g. [84, 63, 64, 175]. These theories, called by their authors “operational”, are purely phenomenological, built on the formal structure of quantum kinematics and usually manifested no interest in the description of specific dynamics of the considered processes. They are often mathematically highly elaborated, very elegant and probably also useful from the point of view of applications of QM. We were not concentrating ourselves here on these approaches and on the questions motivating them. The avoidance of the problems with the dynamics of the interaction of the measured microsystems with the measuring macroscopic apparatuses indicates that in these phenomenological works one assumes, at least implicitly, the existence of some unknown mechanism of the “wave packet reduction”, or equivalently “wave packet collapse”. This is acceptable from the ‘practical point of view’, because in the usual praxis of manipulations with microsystems (e.g. measurements on them) it is possible to deal with the results (e.g. the outcomes of the measurements) as if the “wave packet reduction” really happened. We are here, however, interested in the problem how this process can be included into a noncontradictory quantum theory. An extensive discussion of these problems by the leading physicists up to 1980’ties contains [331].

The last decades, on the other hand, have seen experiments whose results indicate that the interference of macroscopically different states is possible in suitable conditions, cf. e.g.
[195, 196]. These ‘suitable conditions’ consist, first of all, in sufficient isolation of the considered quantum macro-system from any interactions with surrounding environment, then, of course, in the ability of experimenters to discover some suitable ‘macrointerference detecting’ observable quantity, and finally in the inventiveness of experimenters when constructing the desired measuring apparatus.

Our models described in the sections 7.3, 7.4 and 7.5 of this chapter, mainly inspired by the ideas published in [153], show that in the limit $t_m \to \infty$ the classical-like probability distributions of the measurement results (i.e. probability without mutual interferences of results) can be reached. In these models, apparatuses are treated as quantum collections of infinitely many “small” subsystems, and the time necessary for reaching the “reduction of the wave packet” is infinitely long; also, the convergence to the final states of the apparatuses of “proper mixtures”-type is in these simple models – contrary to the ideal requirements – very slow.

The last of our models described in Sec.7.6 shows, however, that if we construct an “apparatus” as a large but finite collection of microsystems, interacting, moreover, with the environment by radiating a particle, the convergence proceeds fast enough – in the sense ‘almost exponentially’. The problem here is nonvanishing possibility of interference of states with different pointer positions, although such a possibility would be for ‘sufficiently large’ apparatuses very improbable. Again, an opened question is the existence and location of a possible borderline for the validity of QM. A mathematically clear formulation of the dependence of possible interferences between macroscopic states of a “large system” on its size will be, probably, a subject of future investigations in theoretical physics. One cannot exclude, however, that there is no sharp borderline between QM and CM, and instead, there is a continuous transition from QM to CM dependent on more parameters than just the size of the measuring apparatus. Or, that there is no borderline at all, QM is a universal theory, but our understanding of its possible applications requires some completions.
